Model parameters

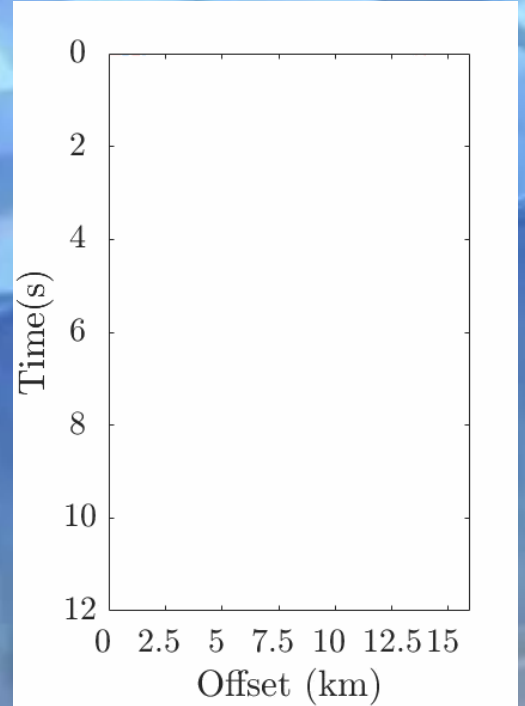

Partial wavefield measurements or recorded data

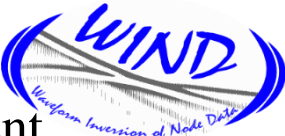

Problem statement: an exploration seismology example

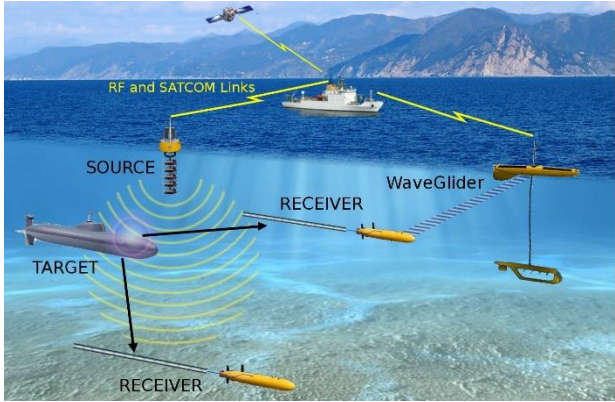

FWI

Applications of FWI (1/2)

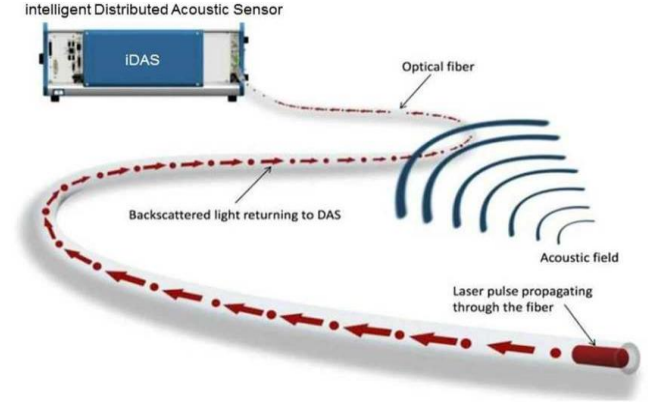

FWI offers an important method for **modelling and remote sensing** from sparse measurements in different fields of applications.

Oceanography (Understanding of the ocean turbulence phenomenon)

Nondestructive testing (Corrosion monitoring)

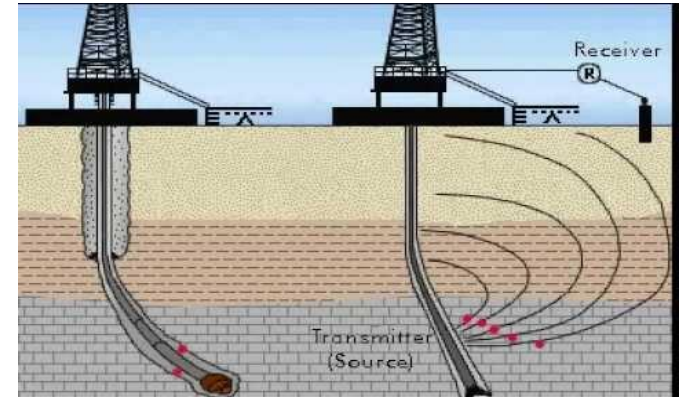

Distributed Acoustic Sensing

Geotechnical investigation

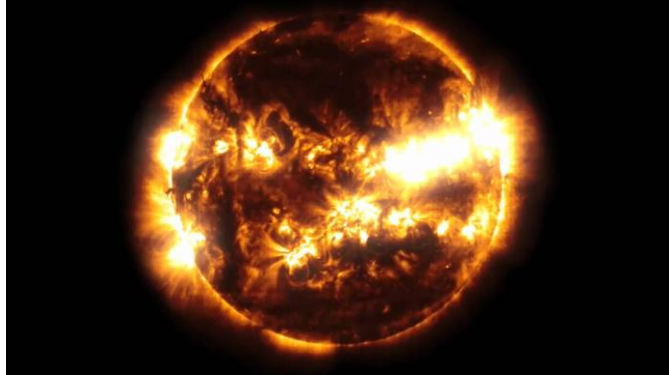

Electrical Resistivity Tomography (ERT)

Seismic while drilling

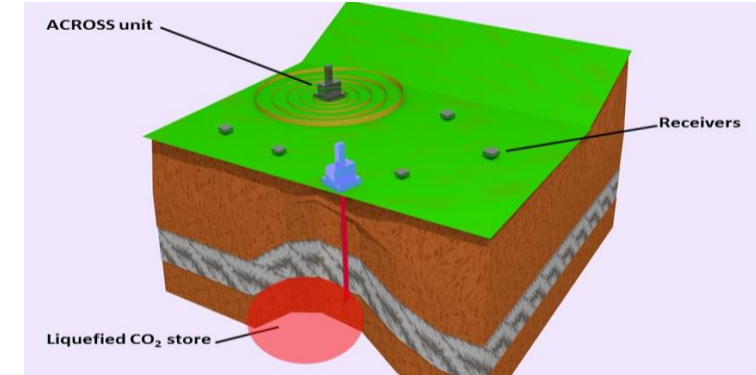

FWI offers an important method for **modelling and remote sensing** from sparse measurements in different fields of applications.

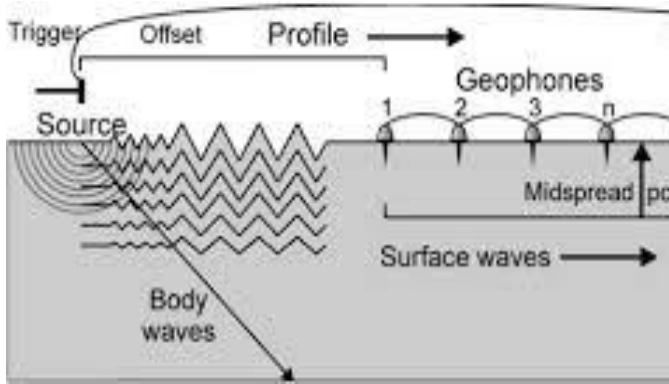

Helioseismology (study of the structure and dynamics of the sun)

Glaciology (the study of ice)

CO₂ monitoring

Surface waves inversion

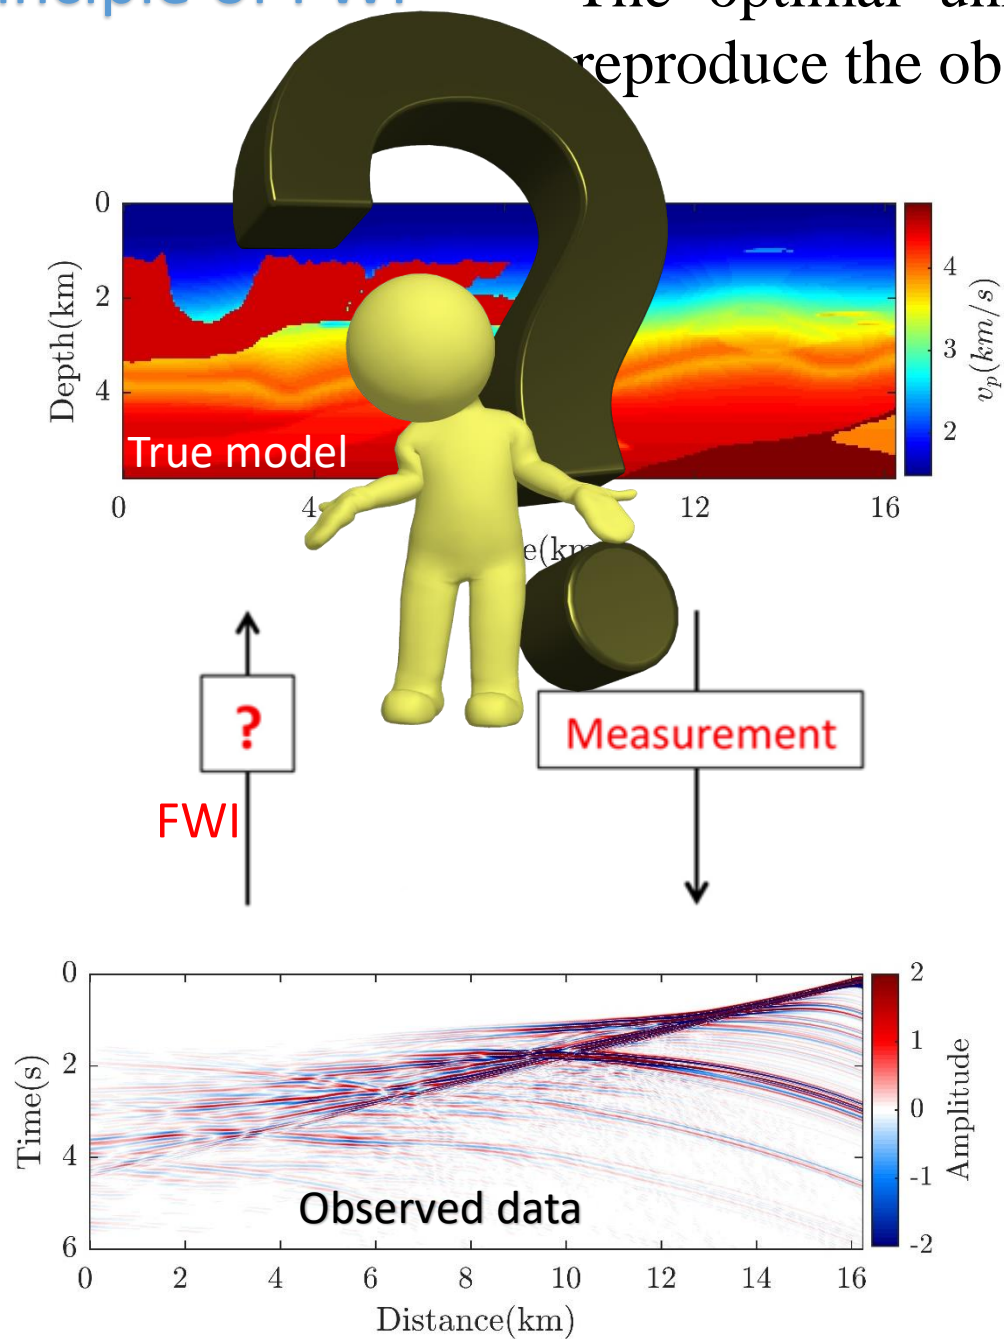

FWI offers an important method for **modelling and remote sensing** from sparse measurements in different fields of applications.

	Exploration seismology	Earthquake seismology	Medical ultrasonic	Electromagnetic (GPR)
Maximum propagation distance	200 km	3000 km	15 cm	60 m
Frequencies	1.5 Hz-80 Hz	0.05 Hz- 1 Hz	1 Mhz- 3 Mhz	10 Mhz-2.6 Ghz
Wavespeed	1500 m/s-8200 m/s	1500 m/s-11000 m/s	1500 m/s-2500 m/s	3e8-4e8
Wavelength	20 m- 5000 m	1.5 km-220 km	0.0005m-0.0025 m	15cm-30m
Number of wavelengths	40-10000	13.63-2000	60-300	2-400
Illumination	Surface	Surface	Circular	Surface

Table 1: A comparison of kinematic scaling parameters in Seismology, ultrasonic medical imaging and electromagnetic imaging. Inspired from [Pratt, 2018].

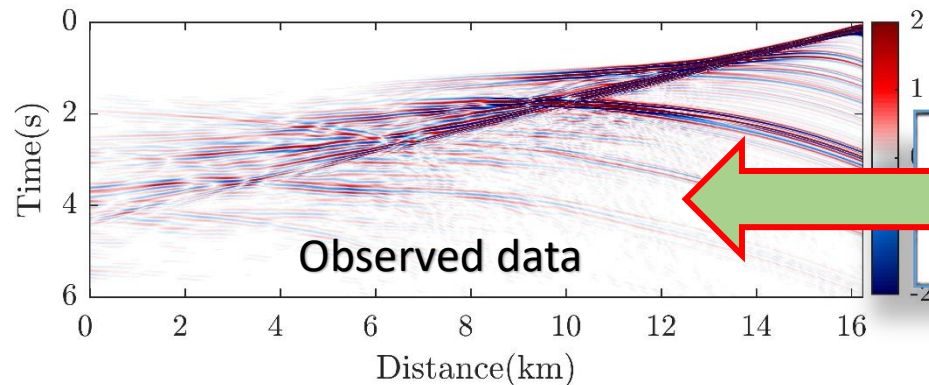

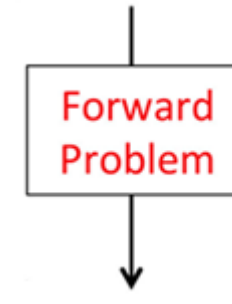

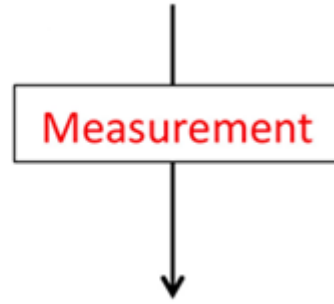

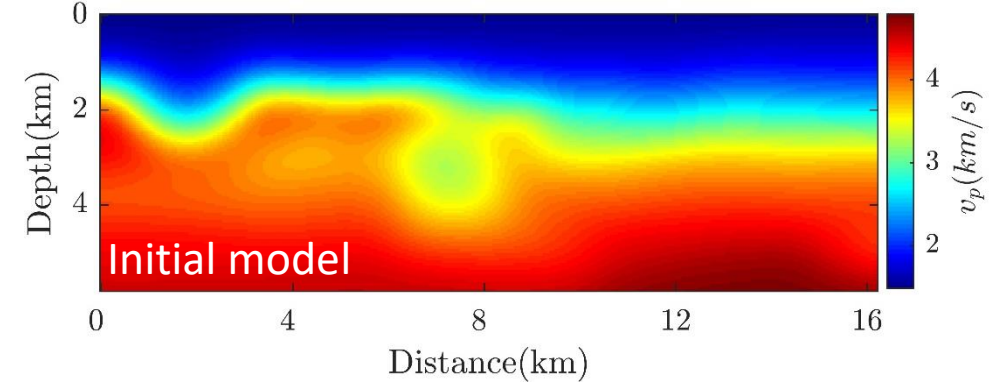

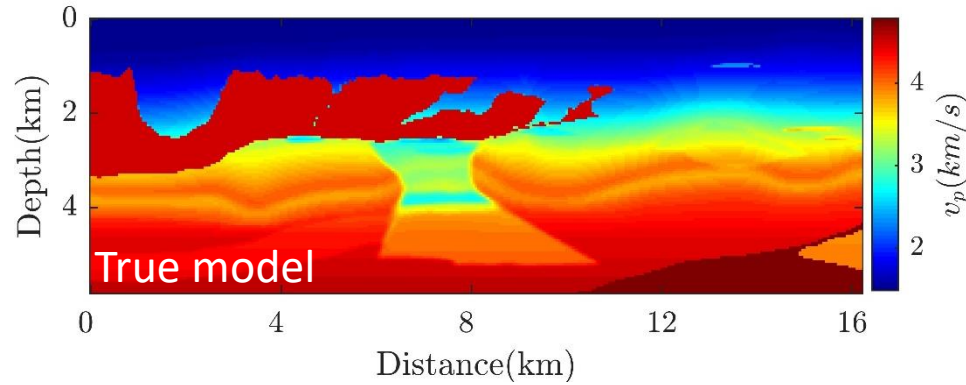

The optimal unknown model is the one that can reproduce the observed data.

The optimal unknown model is the one that can reproduce the observed data.

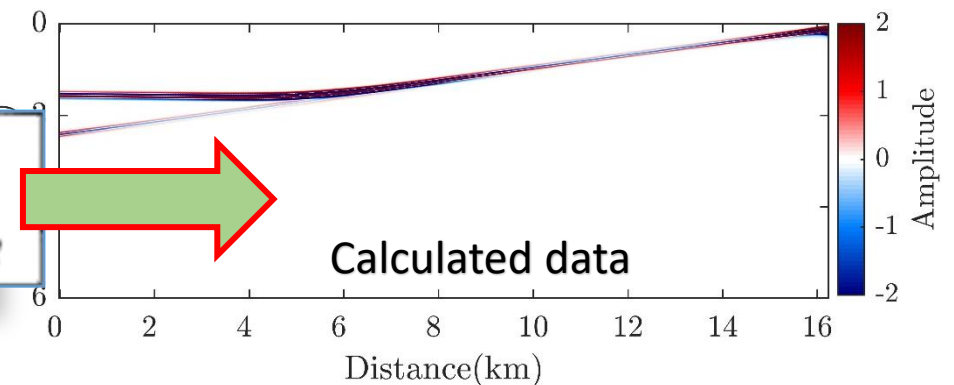

The optimal unknown model is the one that can reproduce the observed data.

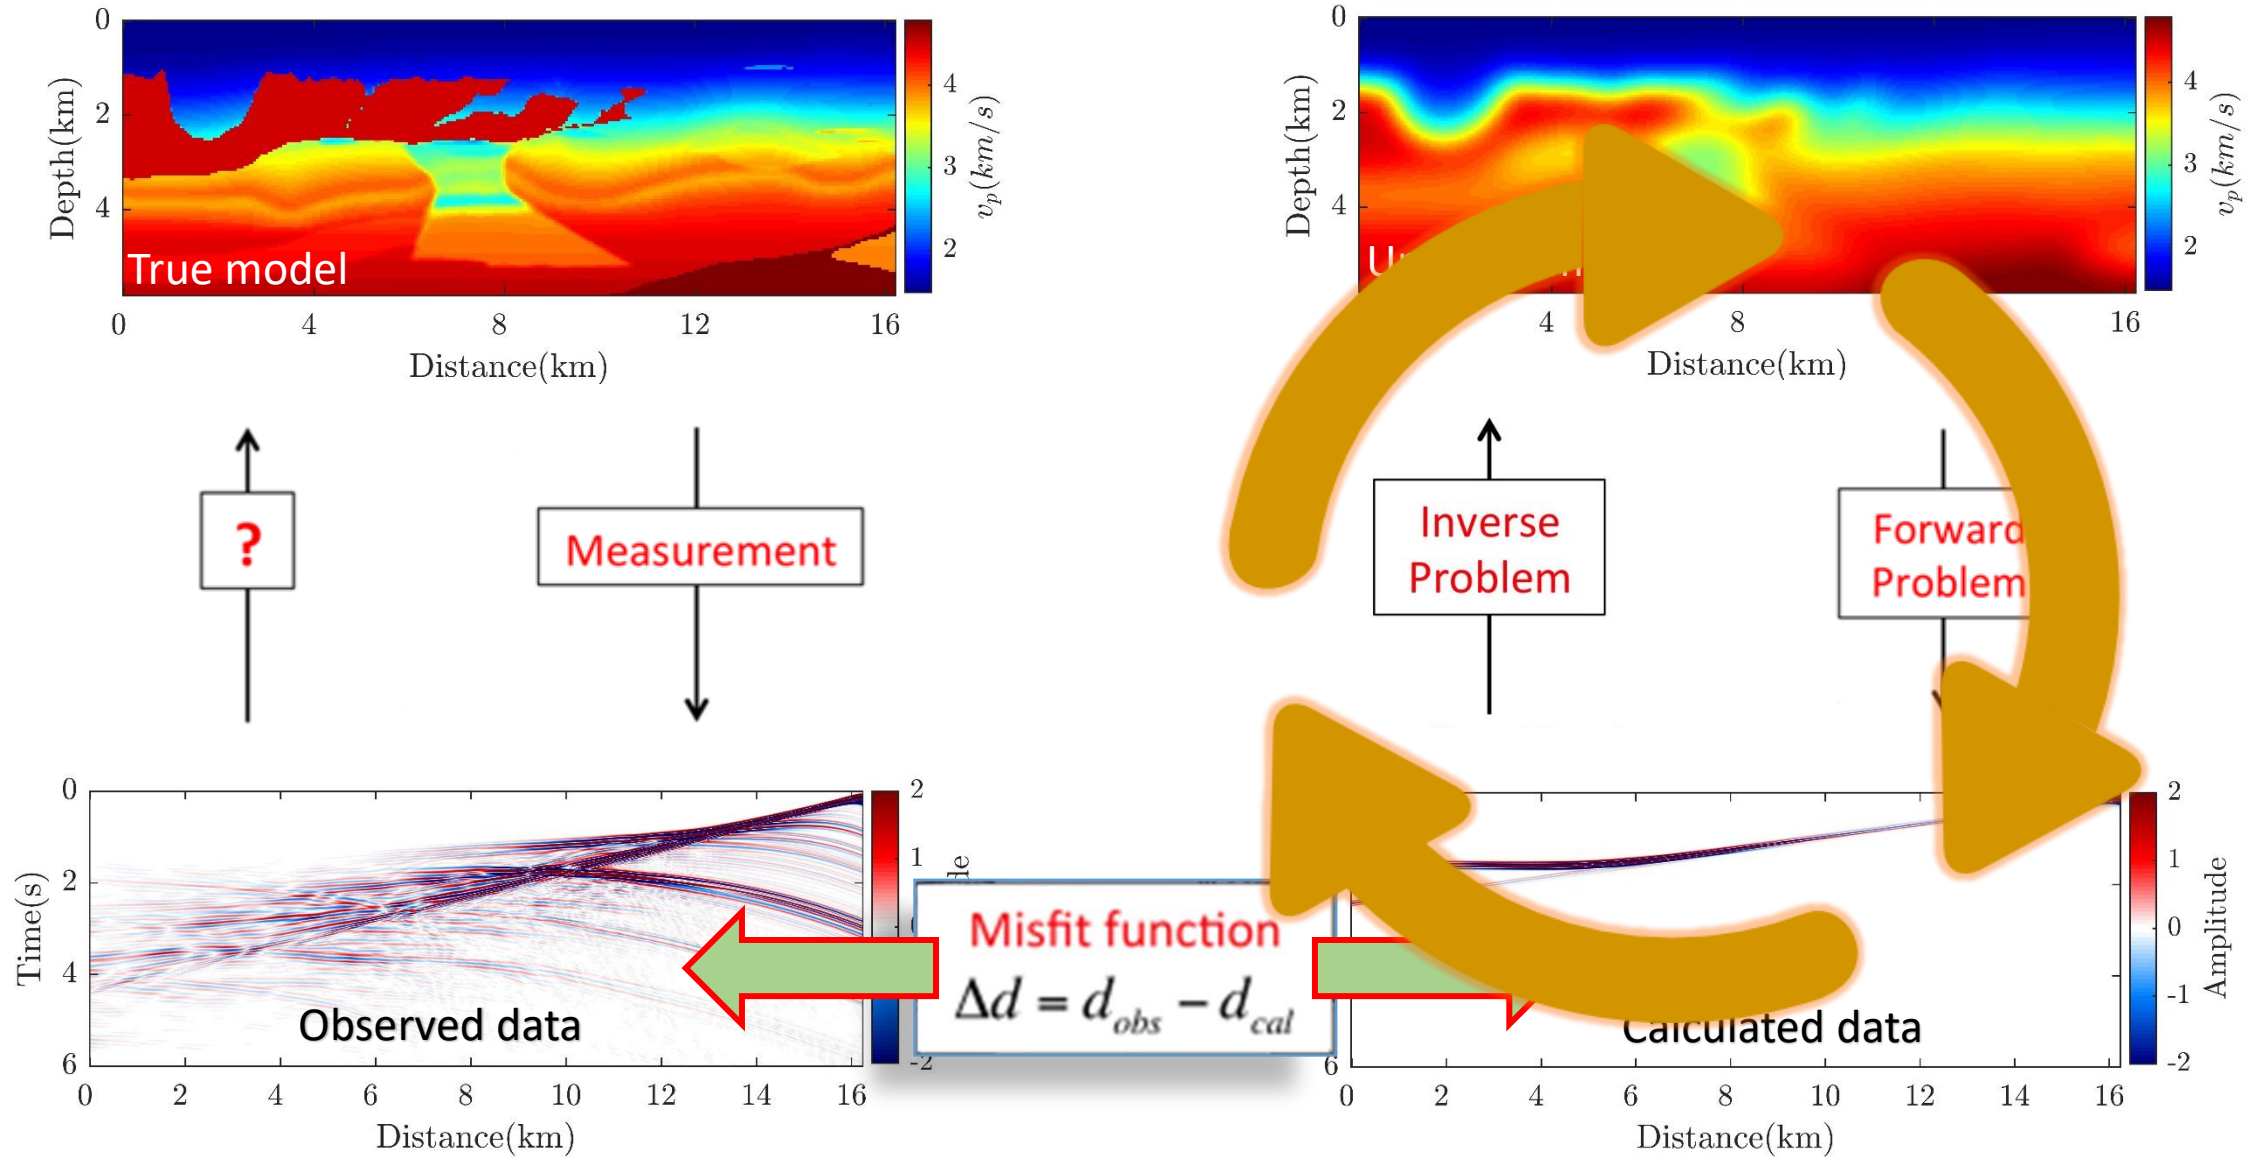

Misfit function

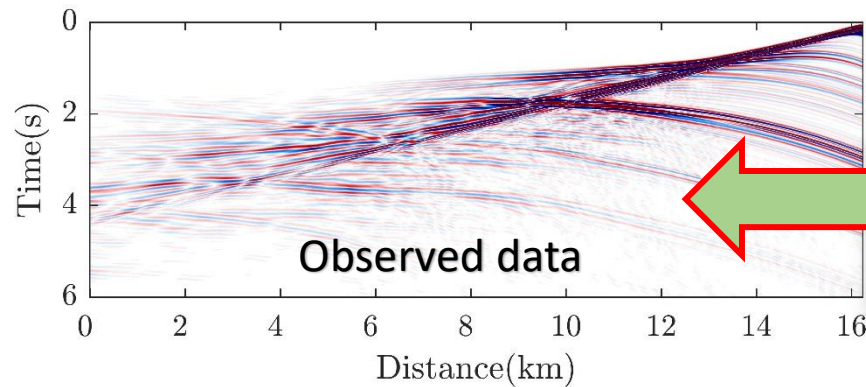

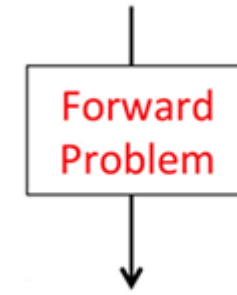

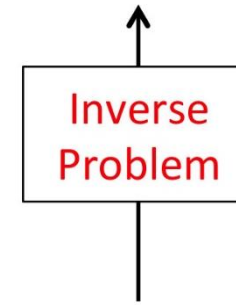

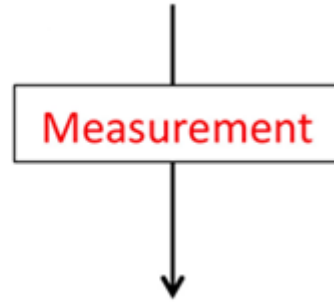

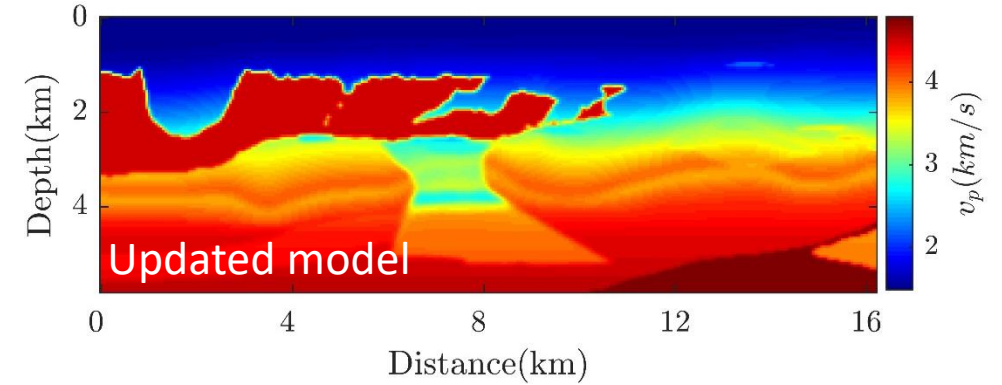

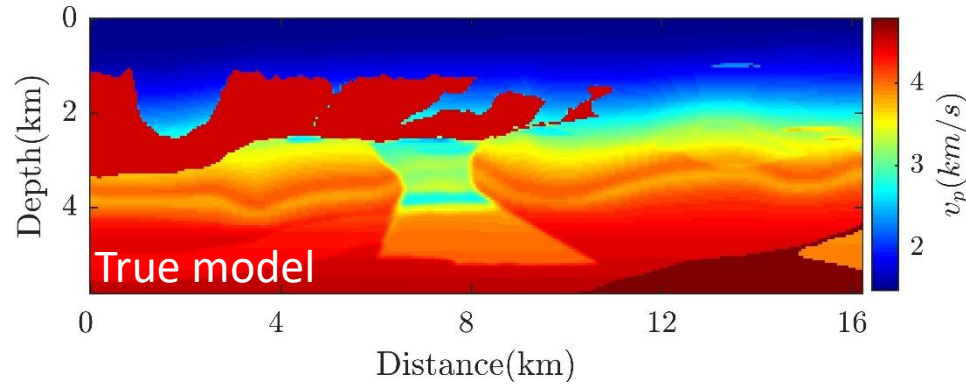

$$\Delta d = d_{obs} - d_{cal}$$

The optimal unknown model is the one that can reproduce the observed data.

FWI from mathematical point of view (Tarantola, 1984)

FWI is a **non-linear (bi-linear)** ill-posed PDE-constrained optimization problem:

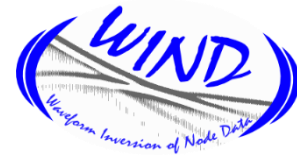

$$\min_{\mathbf{m}, \mathbf{u}} \underbrace{\|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2}_{\text{Observation equation}} + \underbrace{\varphi(\mathbf{m})}_{\text{Regularization function}} \quad \text{Subject to} \quad \underbrace{\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b}}_{\text{Wave equation (bilinear term)}}$$

$$\left\{ \begin{array}{l} \mathbf{m} \in \mathbb{R}^{N \times 1} \rightarrow \text{Model parameters} \\ \mathbf{u} \in \mathbb{C}^{N \times 1} \rightarrow \text{Wavefield} \\ \mathbf{b} \in \mathbb{C}^{N \times 1} \rightarrow \text{Source} \\ \mathbf{d} \in \mathbb{C}^{n_r \times 1} \rightarrow \text{Recorded data} \end{array} \right.$$

Some remarks:

- ✓ This equation is quite **general**, and it is the typical form of imaging methods.
- ✓ Most of the time, **b** and **d** are approximately known and we try to **find m**.
- ✓ Sometimes only **d** is approximately known, and we try to **find b and m**.

FWI from mathematical point of view (Tarantola, 1984)

FWI is a **non-linear (bi-linear)** ill-posed PDE-constrained optimization problem:

$$\min_{\mathbf{m}, \mathbf{u}} \underbrace{\|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2}_{\text{Observation equation}} + \underbrace{\varphi(\mathbf{m})}_{\text{Regularization function}} \quad \text{Subject to} \quad \underbrace{\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b}}_{\text{Wave equation (bilinear term)}}$$

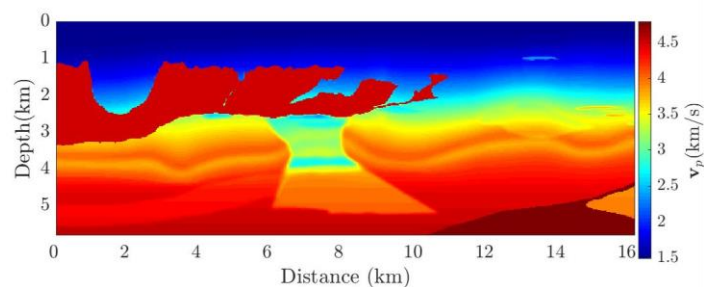

$$\left\{ \begin{array}{l} \mathbf{m} \in \mathbb{R}^{N \times 1} \rightarrow \text{Model parameters} \\ \mathbf{u} \in \mathbb{C}^{N \times 1} \rightarrow \text{Wavefield} \\ \mathbf{b} \in \mathbb{C}^{N \times 1} \rightarrow \text{Source} \\ \mathbf{d} \in \mathbb{C}^{n_r \times 1} \rightarrow \text{Recorded data} \end{array} \right.$$

$\Delta \rightarrow$ Laplacian
 $\omega \rightarrow$ Frequency
 $\text{diag}(\blacksquare) \rightarrow$ a diagonal matrix

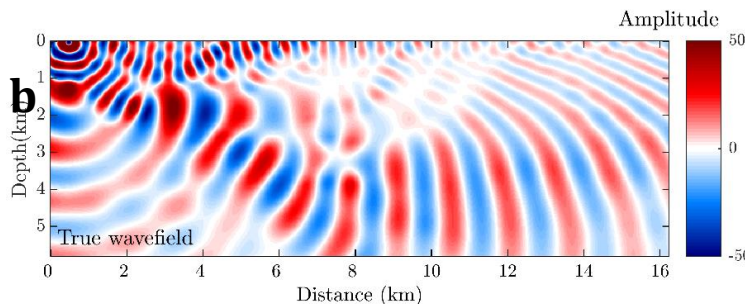

$$\mathbf{A}(\mathbf{m}) = \Delta + \omega^2 \text{diag}(\mathbf{m}) \quad \text{Bilinear}$$

$$\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b} \rightarrow \Delta\mathbf{u} + \omega^2 \text{diag}(\mathbf{m})\mathbf{u} = \mathbf{b} \rightarrow \underbrace{\omega^2 \text{diag}(\mathbf{u})\mathbf{m}}_{\mathbf{L}(\mathbf{u})} = \underbrace{\mathbf{b} - \Delta\mathbf{u}}_{\mathbf{y}}$$

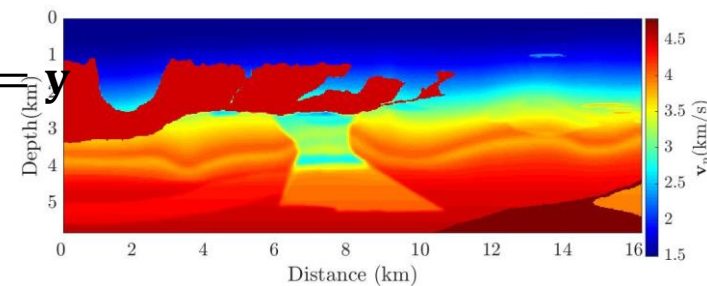

With fixed $\mathbf{m} \rightarrow$ a linear system for \mathbf{u} , and, with fixed $\mathbf{u} \rightarrow$ a linear system for \mathbf{m}

$$\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b}$$

$$\mathbf{L}(\mathbf{u})\mathbf{m} = \mathbf{y}$$

FWI is a **non-linear (bi-linear)** ill-posed PDE-constrained optimization problem:

$$\min_{\mathbf{m}, \mathbf{u}} \underbrace{\|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2}_{\text{Observation equation}} + \underbrace{\varphi(\mathbf{m})}_{\text{Regularization function}} \quad \text{Subject to} \quad \underbrace{\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b}}_{\text{Wave equation (bilinear term)}}$$

$$\left\{ \begin{array}{l} \mathbf{m} \in \mathbb{R}^{N \times 1} \rightarrow \text{Model parameters} \\ \mathbf{u} \in \mathbb{C}^{N \times 1} \rightarrow \text{Wavefield} \\ \mathbf{b} \in \mathbb{C}^{N \times 1} \rightarrow \text{Source} \\ \mathbf{d} \in \mathbb{C}^{n_r \times 1} \rightarrow \text{Recorded data} \end{array} \right.$$

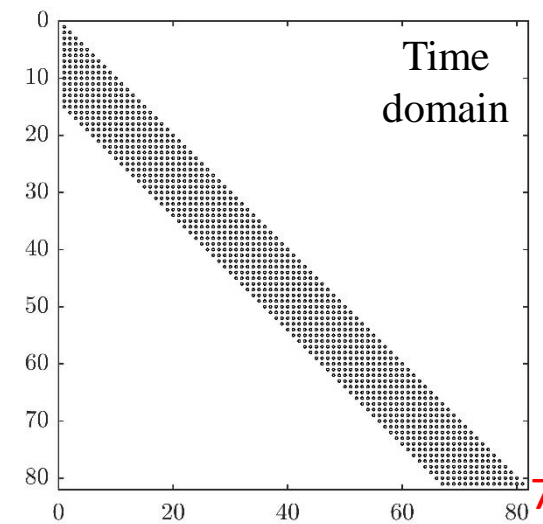

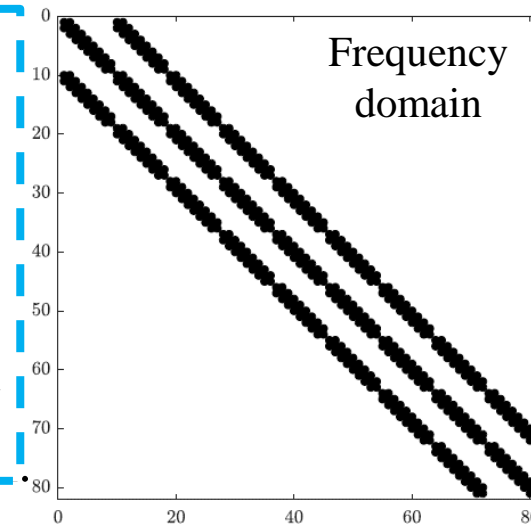

$\Delta \rightarrow$ Laplacian
 $\omega \rightarrow$ Frequency
 $\text{diag}(\blacksquare) \rightarrow$ a diagonal matrix

$$\mathbf{A}(\mathbf{m}) = \Delta + \omega^2 \text{diag}(\mathbf{m}) \quad \text{Bilinear}$$

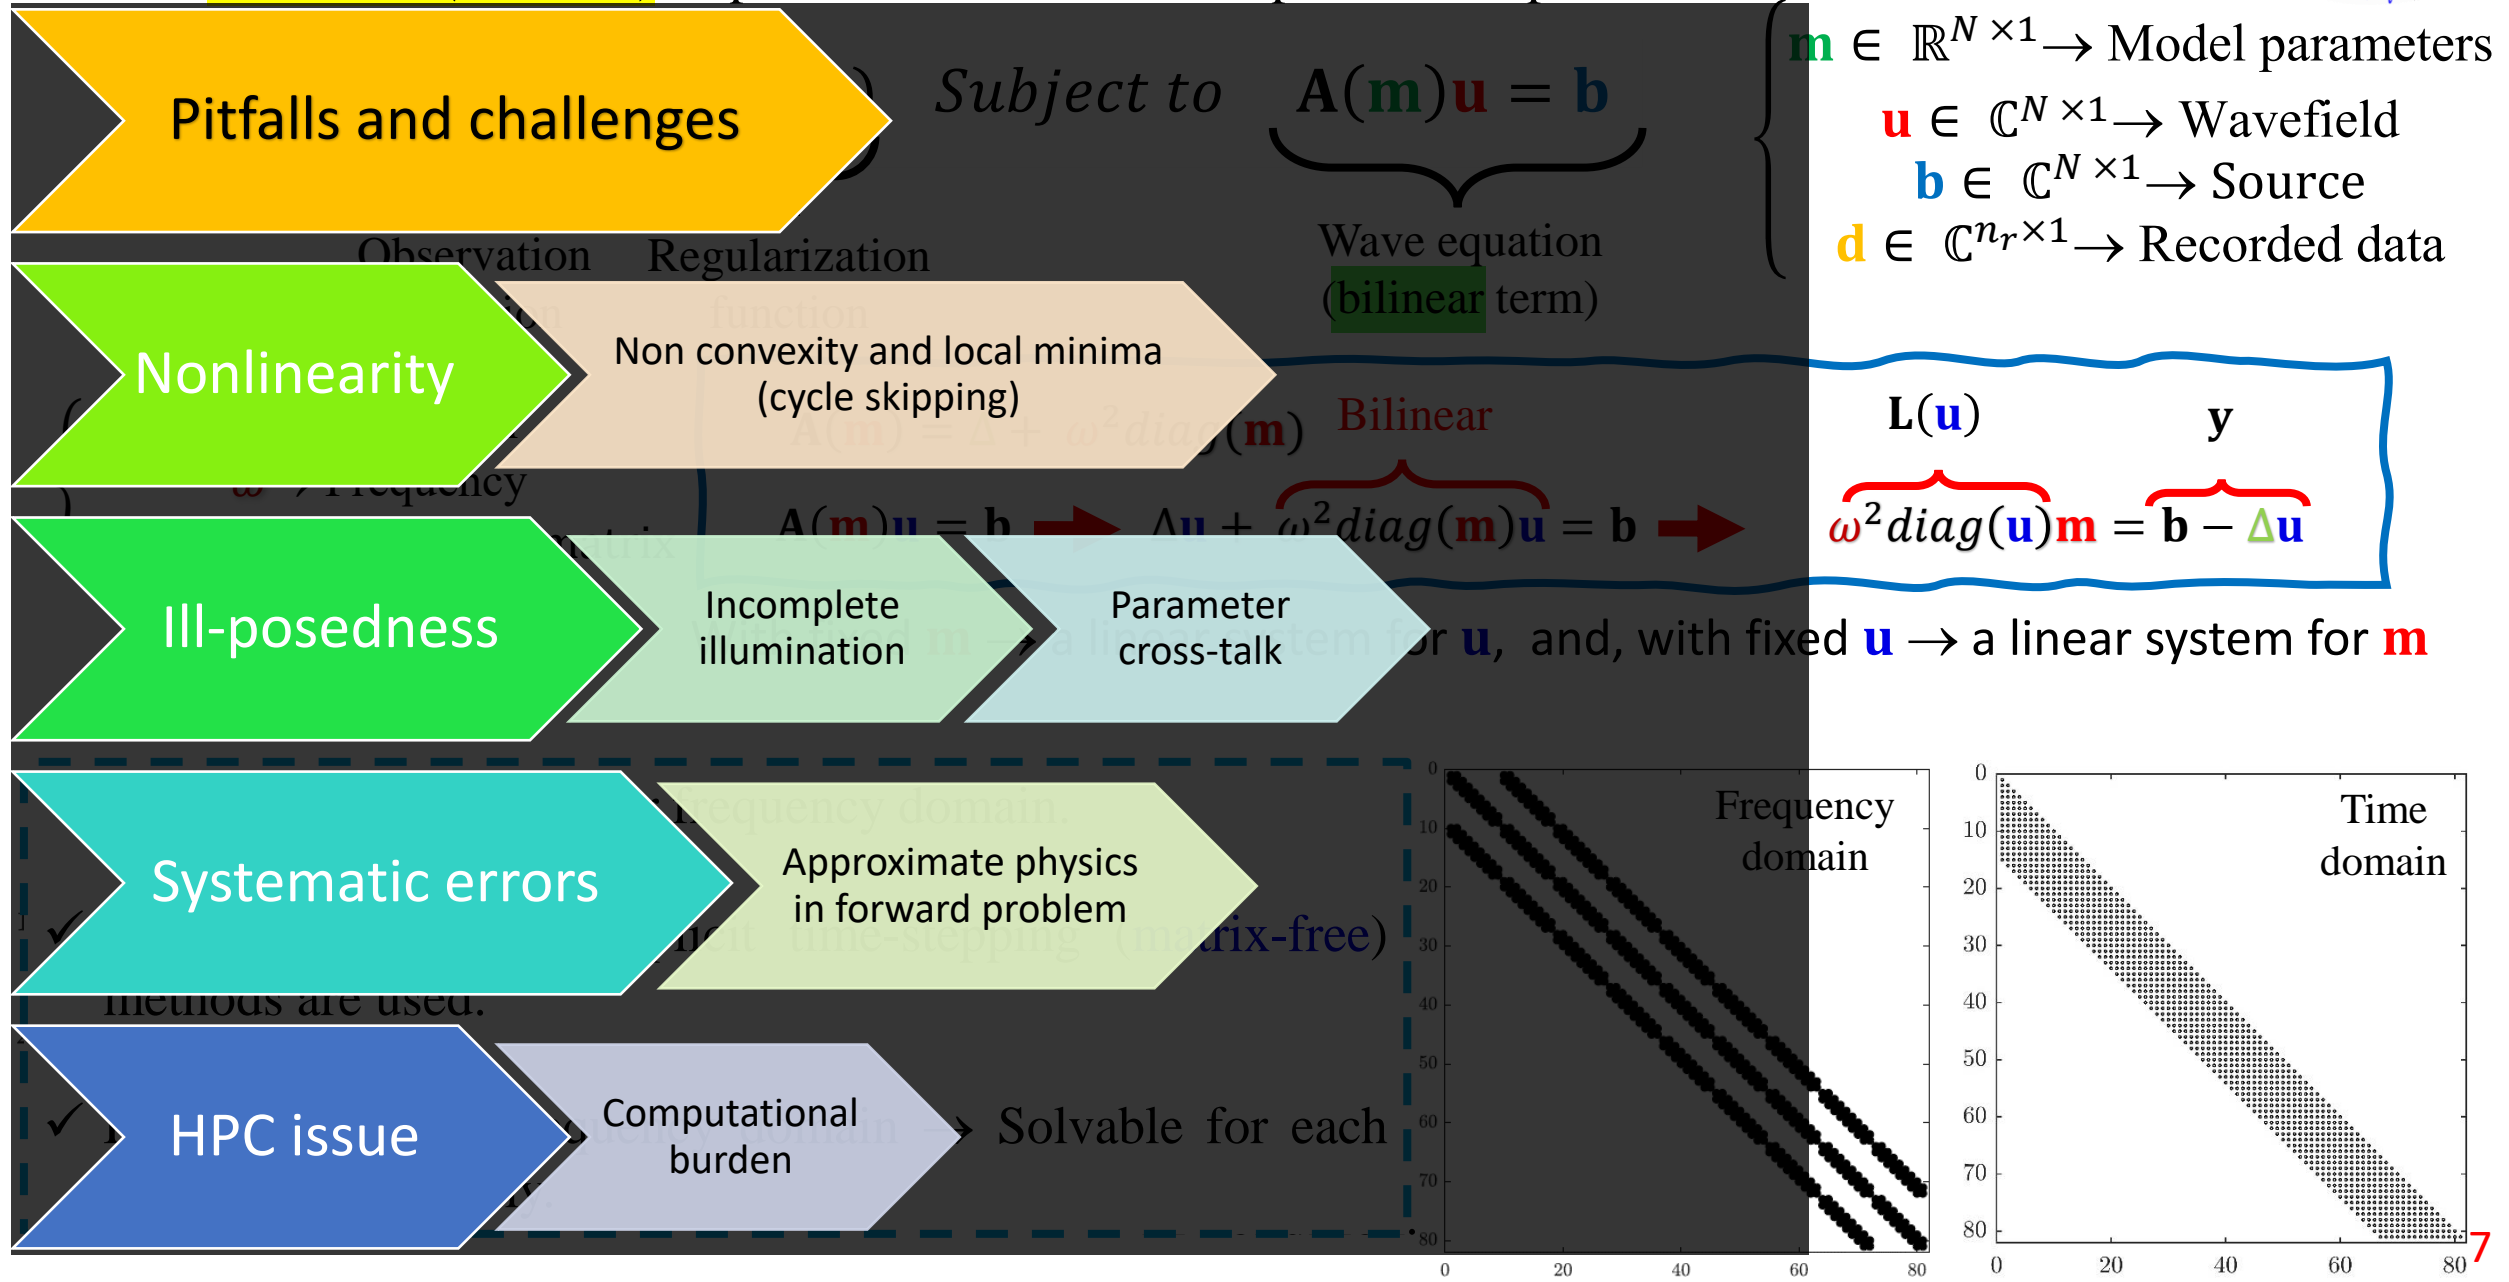

$$\mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b} \rightarrow \Delta\mathbf{u} + \omega^2 \text{diag}(\mathbf{m})\mathbf{u} = \mathbf{b} \rightarrow \omega^2 \text{diag}(\mathbf{u})\mathbf{m} = \mathbf{b} - \Delta\mathbf{u}$$

With fixed $\mathbf{m} \rightarrow$ a linear system for \mathbf{u} , and, with fixed $\mathbf{u} \rightarrow$ a linear system for \mathbf{m}

- ✓ It can be solved in time or frequency domain.
- ✓ In time-domain, the explicit time-stepping (**matrix-free**) methods are used.
- ✓ It is **separable** in frequency domain \rightarrow Solvable for each frequency separately.

FWI is a **non-linear (bi-linear)** ill-posed PDE-constrained optimization problem:

1 Full waveform inversion (FWI) and its challenges

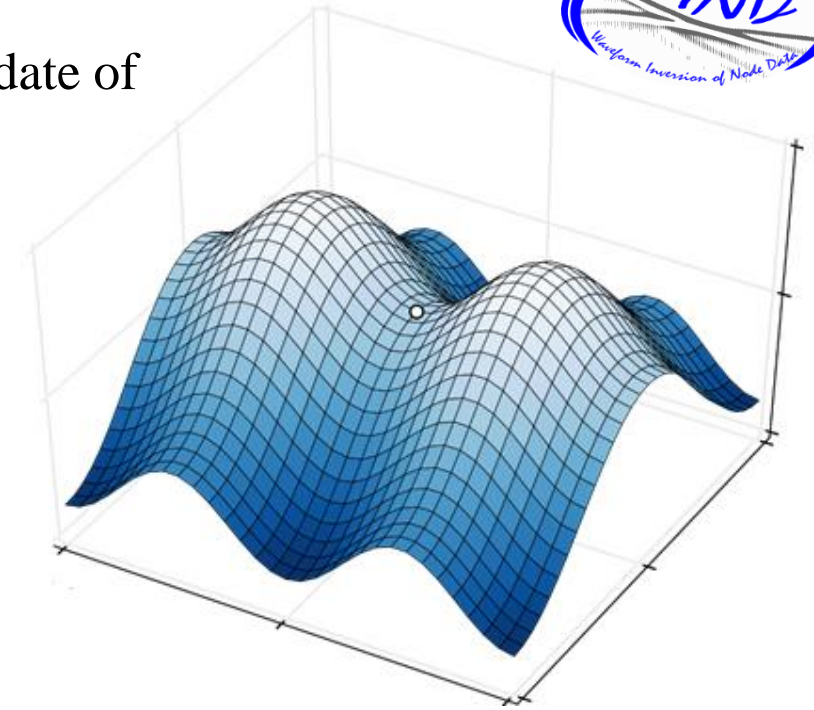

2 Some FWI solution methods

3 Localized FWI or target-oriented FWI

How to solve FWI:

FWI is a **parameter** identification problem for PDE which requires the joint update of **parameter** and the **state variable**.

$$\min_{\mathbf{m}, \mathbf{u}} \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) \quad \text{Subject to} \quad \mathbf{A}(\mathbf{m})\mathbf{u} = \mathbf{b}$$

Some solution methods:

1- Method of Lagrange multipliers

2- Penalty method

3- Method of multipliers (Augmented Lagrangian)

1- Method of Lagrange multipliers

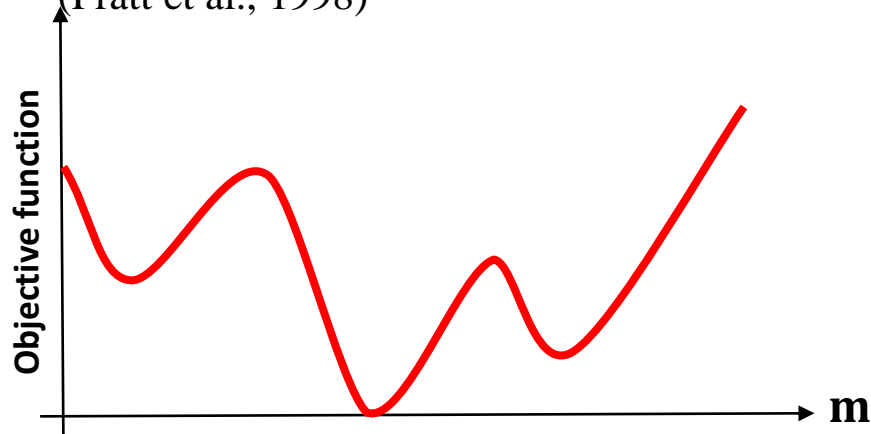

Define the **Lagrangian** function + Determine the partial derivatives (**KKT conditions**) and set them equal to zero.

Lagrangian → $\mathcal{L}(\mathbf{m}, \mathbf{u}, \mathbf{v}) = \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) + \mathbf{v}^T [\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b}]$ $\mathbf{v} \rightarrow$ Lagrange multipliers
(Nocedal & Wright, 2006)

KKT conditions → $\frac{\delta \mathcal{L}(\mathbf{m}, \mathbf{u}, \mathbf{v})}{\delta \mathbf{m}} = 0 \quad \frac{\delta \mathcal{L}(\mathbf{m}, \mathbf{u}, \mathbf{v})}{\delta \mathbf{u}} = 0 \quad \frac{\delta \mathcal{L}(\mathbf{m}, \mathbf{u}, \mathbf{v})}{\delta \mathbf{v}} = 0$

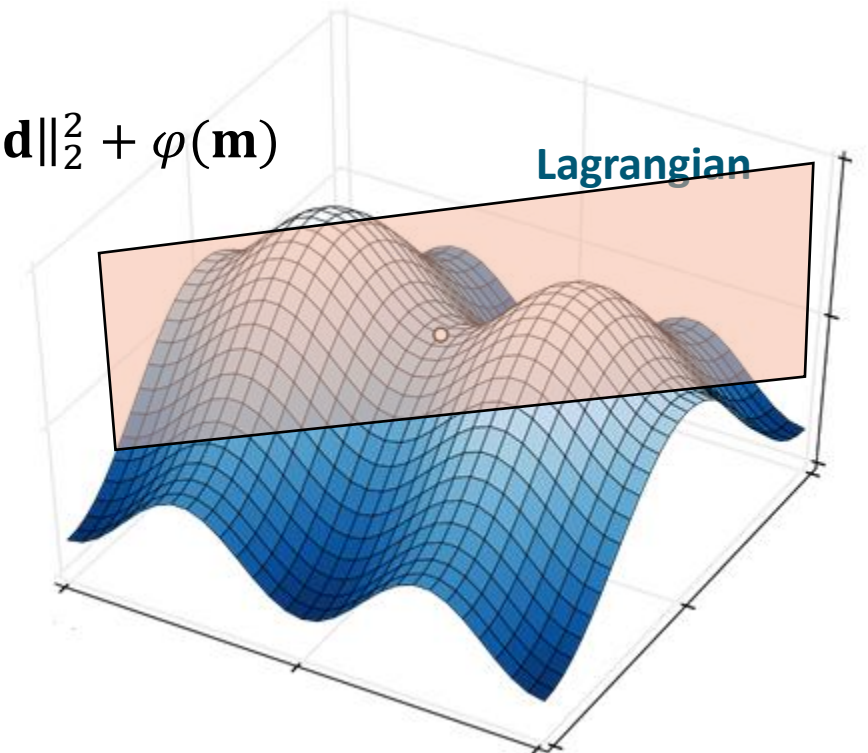

Full space approach → Solve for \mathbf{m} , \mathbf{u} and \mathbf{v} , jointly.
(Haber et al., 2000)

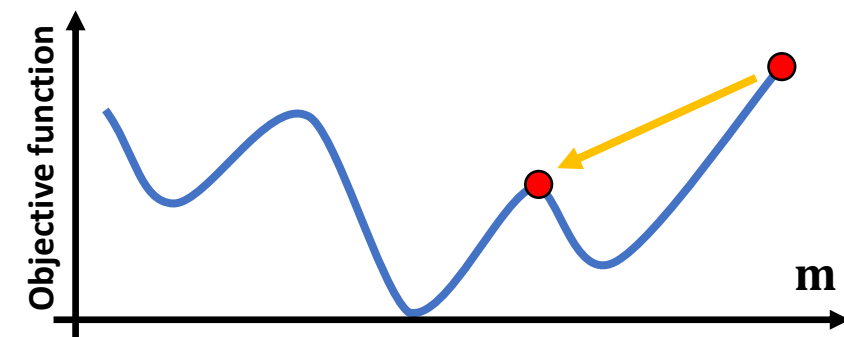

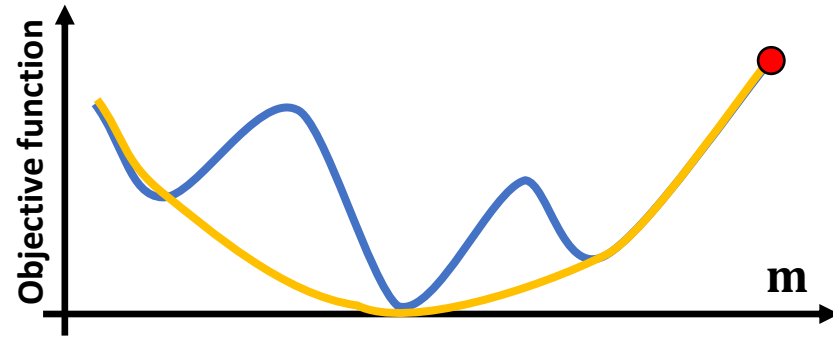

Reduced approach → $\mathbf{u} = \mathbf{A}(\mathbf{m})^{-1}\mathbf{b} \rightarrow \min_{\mathbf{m}} \|\mathbf{P}\mathbf{A}(\mathbf{m})^{-1}\mathbf{b} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m})$
(Pratt et al., 1998)

Reduced approach

It makes the objective function more oscillating.

Modifying the **cost** function:

- ✓ Correlation-based misfit function (Luo & Schuster, 1991).
- ✓ Envelope and instantaneous phase-based misfit function (Fichtner et al., 2008; Luo and Wu, 2015).
- ✓ Dynamic wrapping-based misfit function (Ma and Hale, 2013).
- ✓ Normalized integration-based misfit function (Donno et al., 2013)
- ✓ Optimal transport misfit function (Engquist et al., 2016; Métivier et al., 2106)

Preparing a **good initial** model:

- ✓ Ray-based tomography (Tavakoli et al., 2017, Sambolian et al., 2019)
- ✓ Migration velocity analysis (MVA) (Symes and Kern, 1994)
- ✓ Reflection wavefield inversion (RWI) (Brossier et al., 2015)
- ✓ Global optimization for FWI (Shaw and Srivastava, 2007, Ely et al., 2015, Datta and Sen, 2016, Sajeve et al., 2016, Galuzzi et al., 2017)

Transform a **constrained** optimization problem into a **sequence of unconstrained** optimization subproblems that are easier to solve. By replacing the hard constraint with a soft constraint, we have:

Penalty form→ $C(\mathbf{m}, \mathbf{u}) = \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) + \lambda \|\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b}\|_2^2$

$\lambda \rightarrow$ Penalty parameter

Bi-convex optimizations (Gorski et al., 2007)

- ✓ Basically, **FWI** is a **bi-convex** optimization problem (Aghamiry et al, 2019).
- ✓ Such problems may have **many local minima** as generally they are non-convex optimization problems.

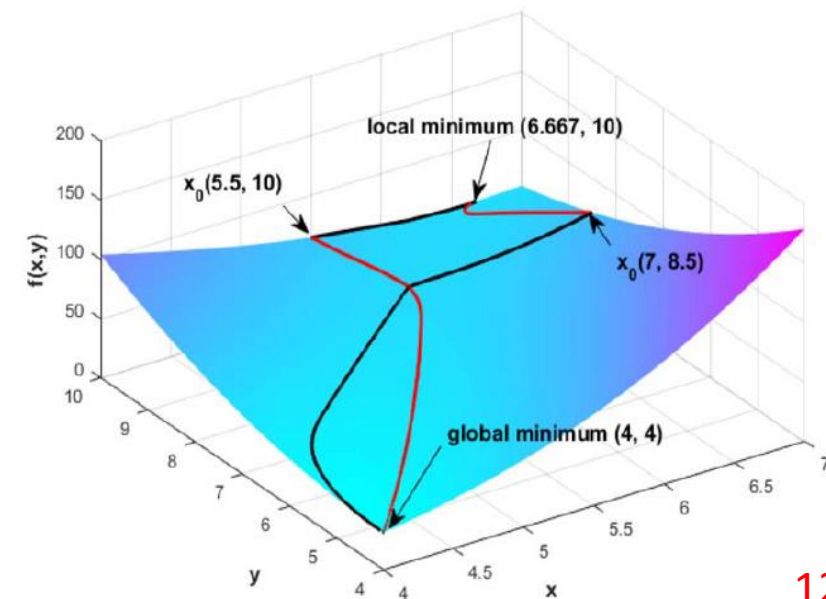

Is it possible to find *the global minimum of a bi-convex optimization?*

Methods for solving biconvex optimization problems

1. General methods that are used for **non-convex optimizations**.
2. The algorithms which **exploit** the **convex subproblems** of a biconvex optimization (Gorski et al., 2007).

2

- ✓ Block relaxation methods, e.g., Alternating Convex set (**ACS**) (de Leeuw, 1994), Alternating direction method of multipliers (**ADMM**) (Boyd et al., 2010) are common methods for solving although they don't have a **convergence proof**.
- ✓ There are some methods, e.g., Global OPTimization algorithm (**GOP**) (Floudas, 2000), with **convergence proof**.

Transform a **constrained** optimization problem into a **sequence of unconstrained** optimization subproblems that are easier to solve. By replacing the hard constraint with a soft constraint, we have:

Penalty form → $C(\mathbf{m}, \mathbf{u}) = \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) + \lambda \|\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b}\|_2^2$

$\lambda \rightarrow$ Penalty parameter

Wavefield reconstruction inversion (WRI) (van Leeuwen&Herrmann, 2013)

Solving the penalty form with *Alternate Convex Search* (**ACS**) (Wendell & Hurter, 1976)

- ACS →
- 1- Keep \mathbf{m} fixed and solve the convex optimization for \mathbf{u} .
 - 2- Keep \mathbf{u} fixed and solve the convex optimization for \mathbf{m} .
 - 3- Check the stopping criterion if it is satisfied

The order of 1 and 2 can be permuted.

$$\min_{\mathbf{u}} C(\mathbf{m}^k, \mathbf{u}) \rightarrow \min_{\mathbf{m}} C(\mathbf{m}, \mathbf{u}^k) \rightarrow \text{stopping criterion}$$

Superscript $k \rightarrow$ mentions to the value of variables \mathbf{m}^k and \mathbf{u}^k at iteration k .

- ✓ **Slow convergence.**
- ✓ Selecting λ is **challenging**.
- ✓ WRI, and generally ACS, may **fail** and **stuck** in local-minima (Symes, 2020).
- ✓ The Lagrange multipliers are scaled versions of wave-equation residuals, i.e., $\mathbf{v} = \lambda(\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b})$, which is **not efficient**.

The method was studied much in the 1970 and 1980s as a good alternative to penalty methods.

Augmented Lagrangian (AL) \rightarrow **Lagrangian** + **a penalty term** (Nocedal & Wright, 2006)

$$\mathcal{L}_A(\mathbf{m}, \mathbf{u}, \mathbf{v}) = \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) + \mathbf{v}^T (\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b}) + \lambda \|\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b}\|_2^2$$

- λ \rightarrow Penalty parameter,
- \mathbf{v} \rightarrow Lagrange multipliers
or dual variables.

Scaled form of AL → Define **scaled form** of dual variables as $\tilde{\mathbf{b}} = -\mathbf{v}/\lambda$ (Boyd et al, 2010).

$$\mathcal{L}_A(\mathbf{m}, \mathbf{u}, \tilde{\mathbf{b}}) = \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \varphi(\mathbf{m}) + \lambda \|\mathbf{A}(\mathbf{m})\mathbf{u} - \mathbf{b} - \tilde{\mathbf{b}}\|_2^2 - \lambda \|\tilde{\mathbf{b}}\|_2^2$$

We prefer the **scaled form** of AL because we can have a **physical interpretation** for dual variables.

ADMM-based FWI (Aghamiry et al., 2018)

ADMM is a **recommended** tool for biconvex optimizations (Boyd et al., 2010; Brás et al., 2012).

ADMM Solves AL in an alternating mode for primal and dual variables as

$$\underbrace{\min_{\mathbf{u}} \mathcal{L}_A(\mathbf{m}^k, \mathbf{u}, \tilde{\mathbf{b}}^k) \rightarrow \min_{\mathbf{m}} \mathcal{L}_A(\mathbf{u}^{k+1}, \mathbf{m}, \tilde{\mathbf{b}}^k)}_{\text{Primals}} \rightarrow \underbrace{\max_{\tilde{\mathbf{b}}} \mathcal{L}_A(\mathbf{u}^{k+1}, \mathbf{m}^{k+1}, \tilde{\mathbf{b}})}_{\text{Dual}}$$

It uses **partial updates of primal variables** (similar to the Gauss–Seidel method for solving linear equations)

How does ADMM-based FWI work?

First subproblem →
$$\mathbf{u}^{k+1} = \underset{\mathbf{u}}{\operatorname{argmin}} \quad \|\mathbf{P}\mathbf{u} - \mathbf{d}\|_2^2 + \lambda \|\mathbf{A}(\mathbf{m}^k)\mathbf{u} - \mathbf{b} - \tilde{\mathbf{b}}^k\|_2^2$$
$$\begin{bmatrix} \mathbf{P} \\ \sqrt{\lambda}\mathbf{A}(\mathbf{m}^k) \end{bmatrix} \mathbf{u}^{k+1} = \begin{bmatrix} \mathbf{d} \\ \sqrt{\lambda}[\mathbf{b} + \tilde{\mathbf{b}}^k] \end{bmatrix}$$

1

- ✓ Solve **wave equation** with a **feedback** term from **data** → *data assimilated* wavefield (Auroux & Blum, 2008).
- ✓ **Extrapolation** problem with a **feedback** term from **physics**.

Second subproblem →
$$\mathbf{m}^{k+1} = \underset{\mathbf{m}}{\operatorname{argmin}} \quad \varphi(\mathbf{m}) + \lambda \|\mathbf{L}(\mathbf{u}^{k+1})\mathbf{m} - \mathbf{y}\|_2^2$$

- ✓ **Push back** \mathbf{u}^{k+1} toward the **wave equation** + satisfy the **regularization**.

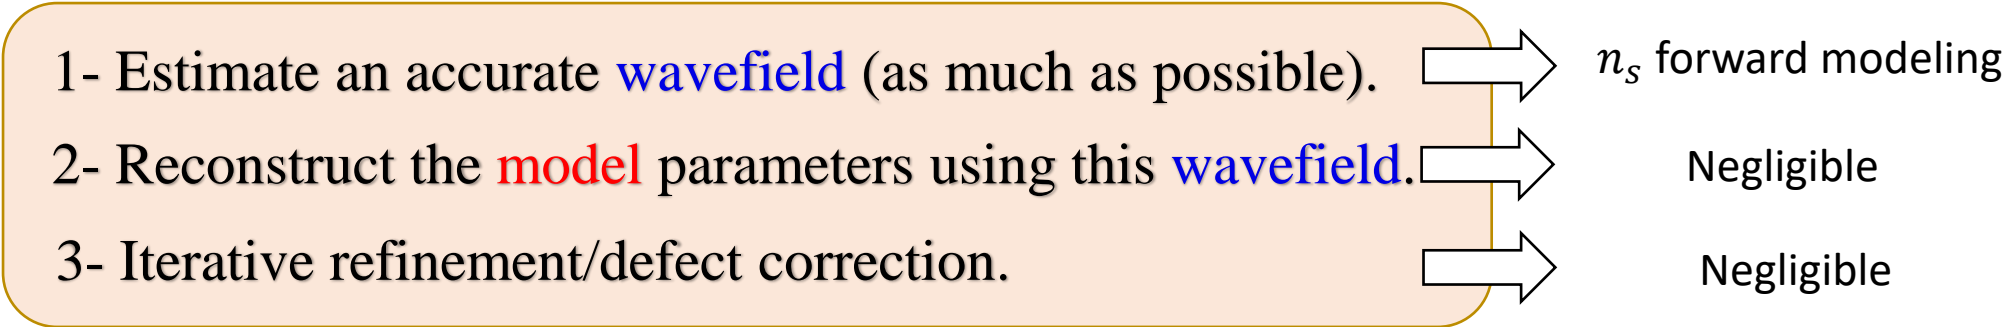

2

Third subproblem →
$$\tilde{\mathbf{b}}^{k+1} = \tilde{\mathbf{b}}^k + \mathbf{b} - \mathbf{A}(\mathbf{m}^{k+1})\mathbf{u}^{k+1}$$

- ✓ Updating the RHS by the **running sum of wave-equation error**.

3

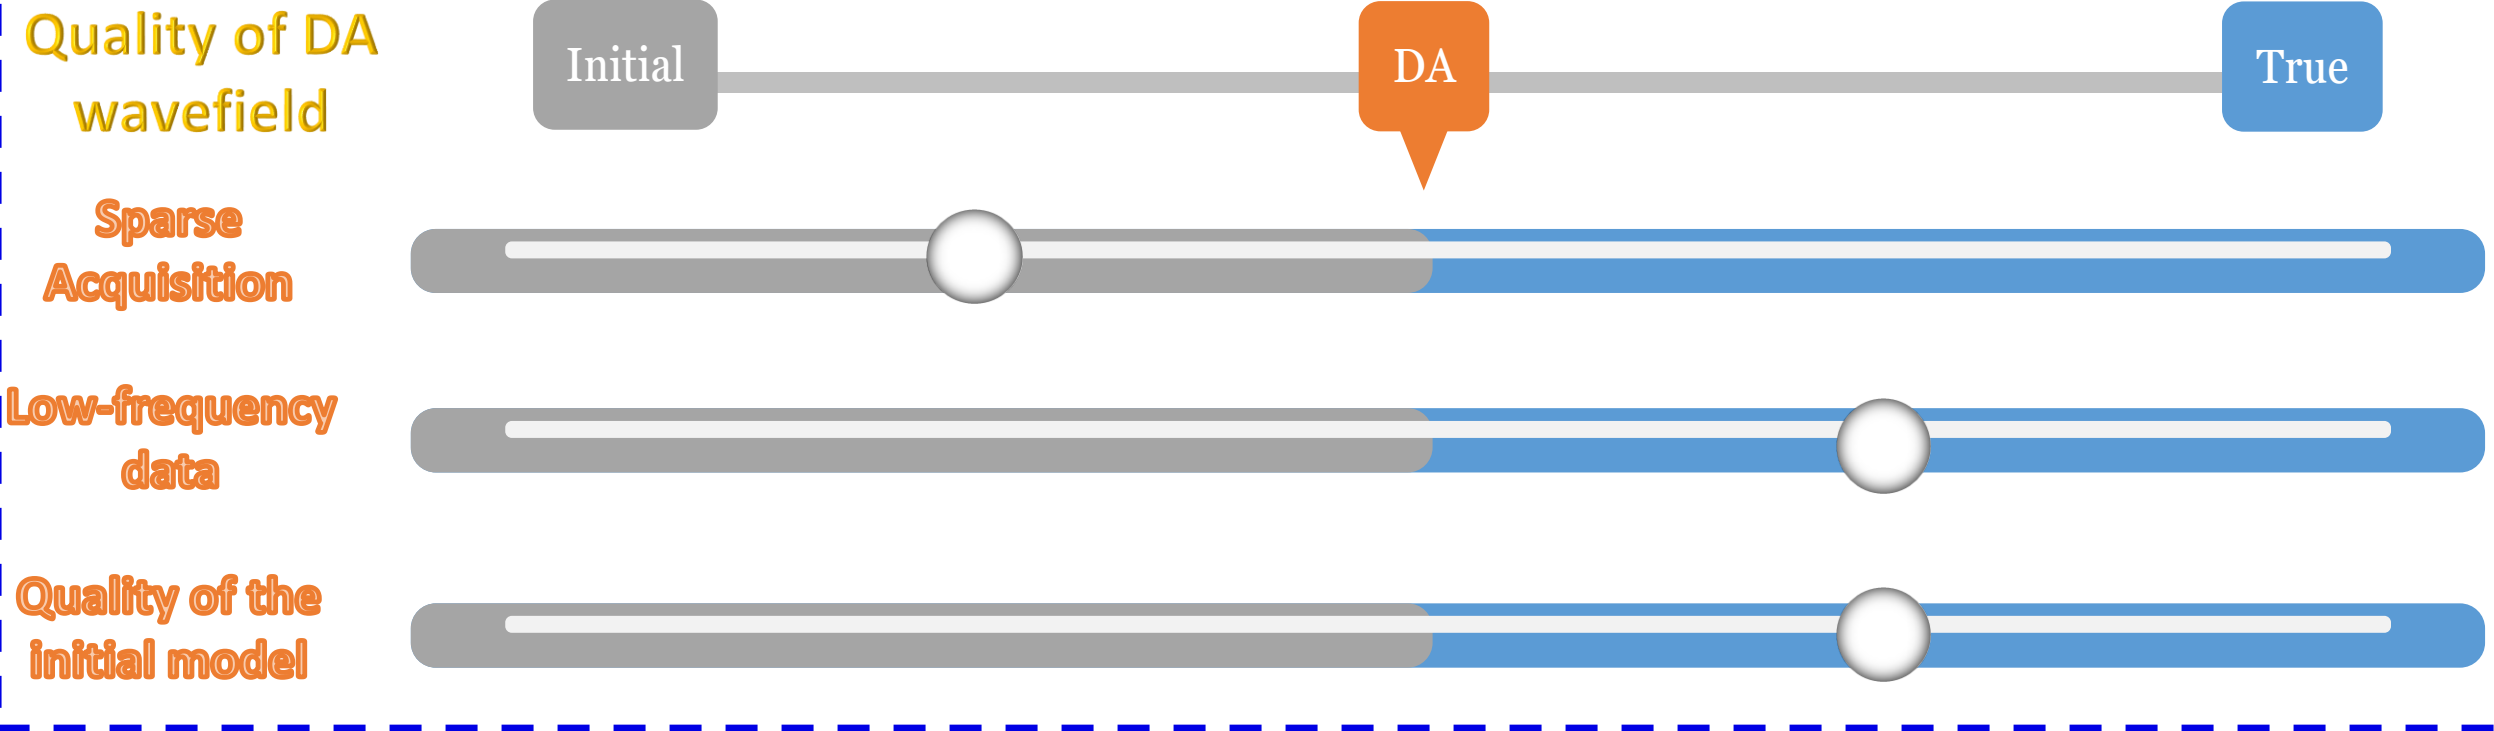

Mechanism →

The challenges of the method

- ✓ We don't know under which conditions the method works.

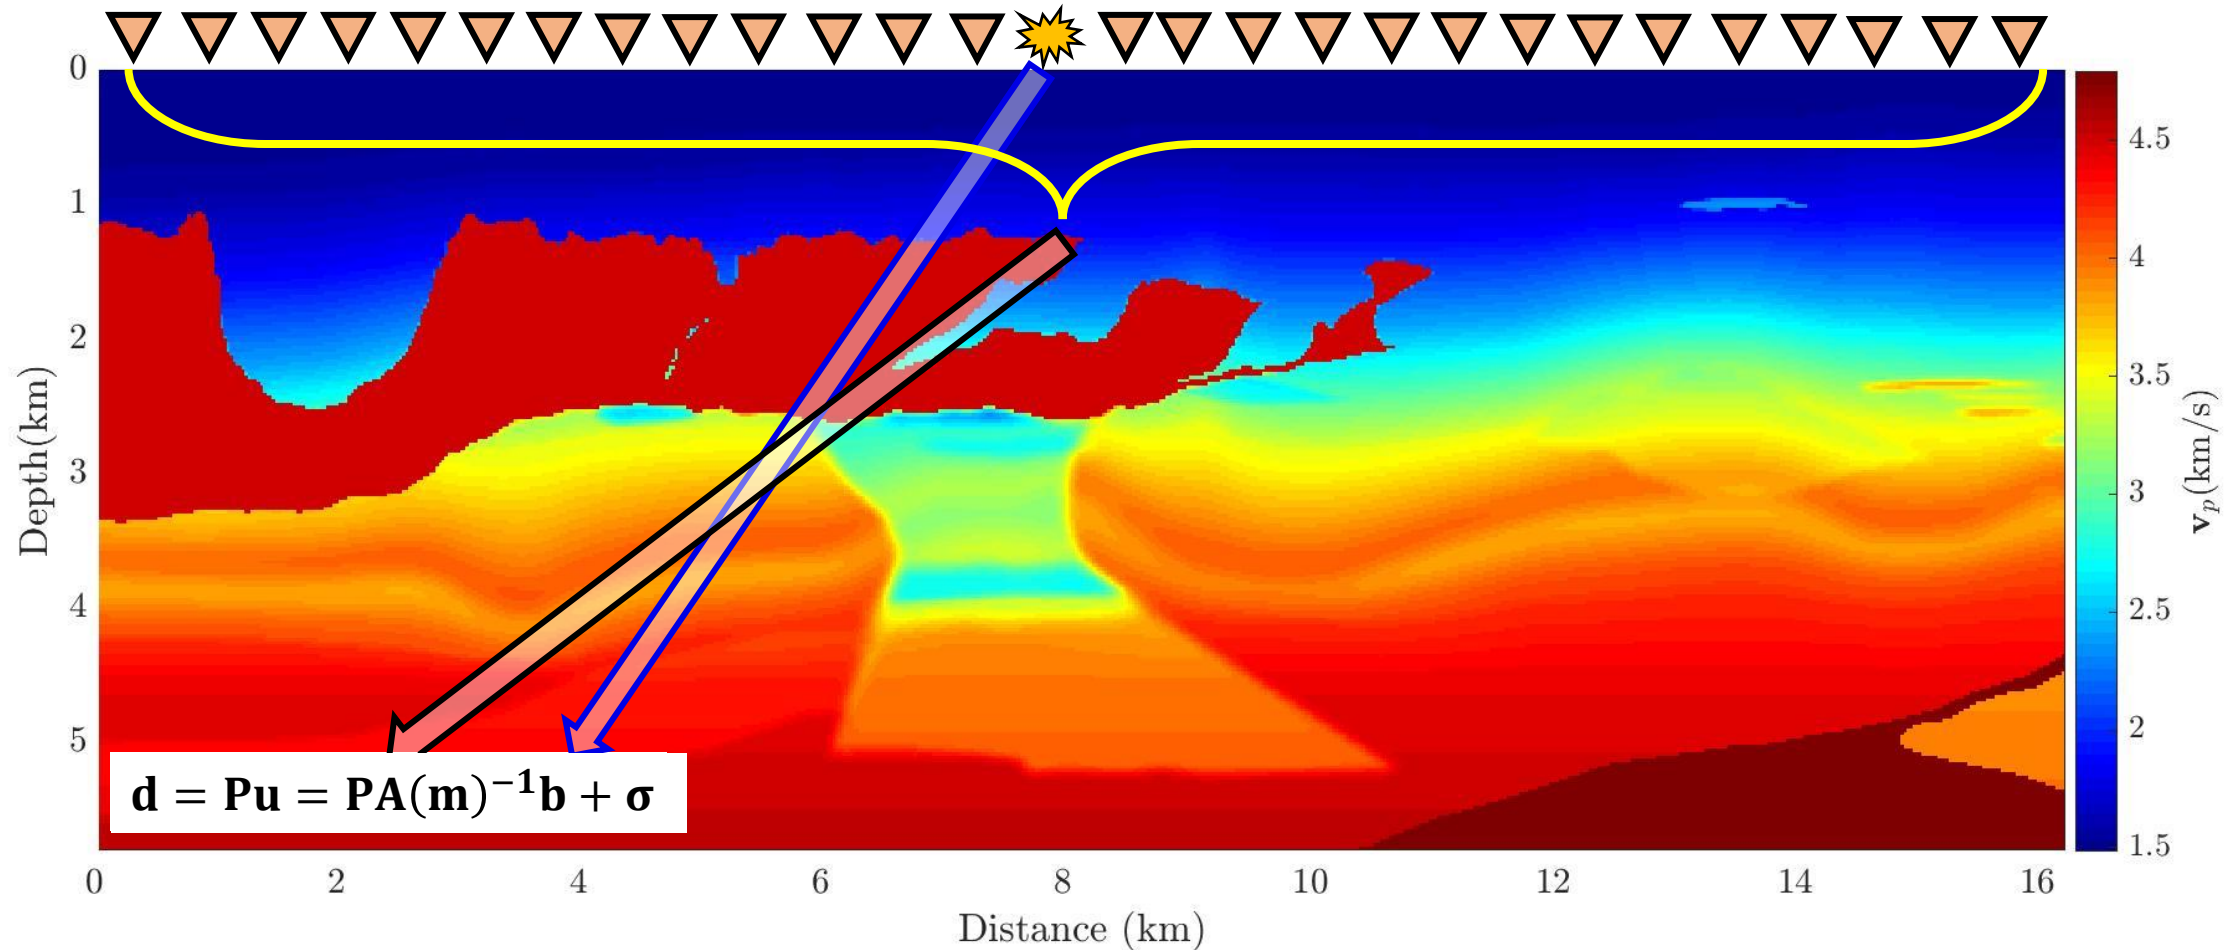

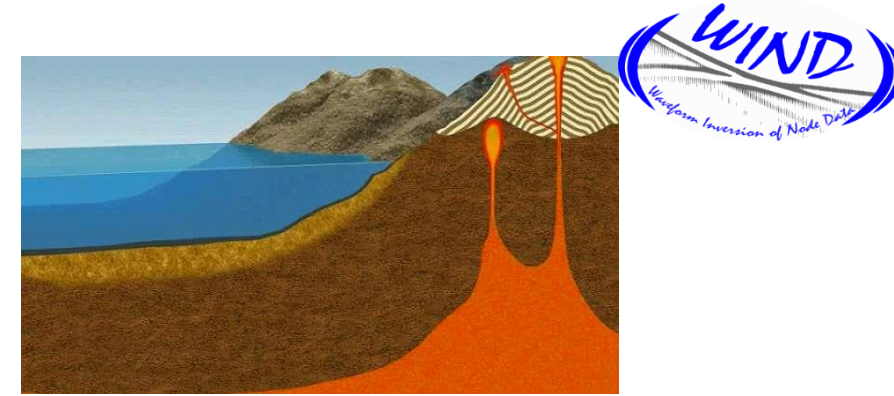

Qualitatively, we know the DA wavefield should be close to the true wavefield near the receivers.

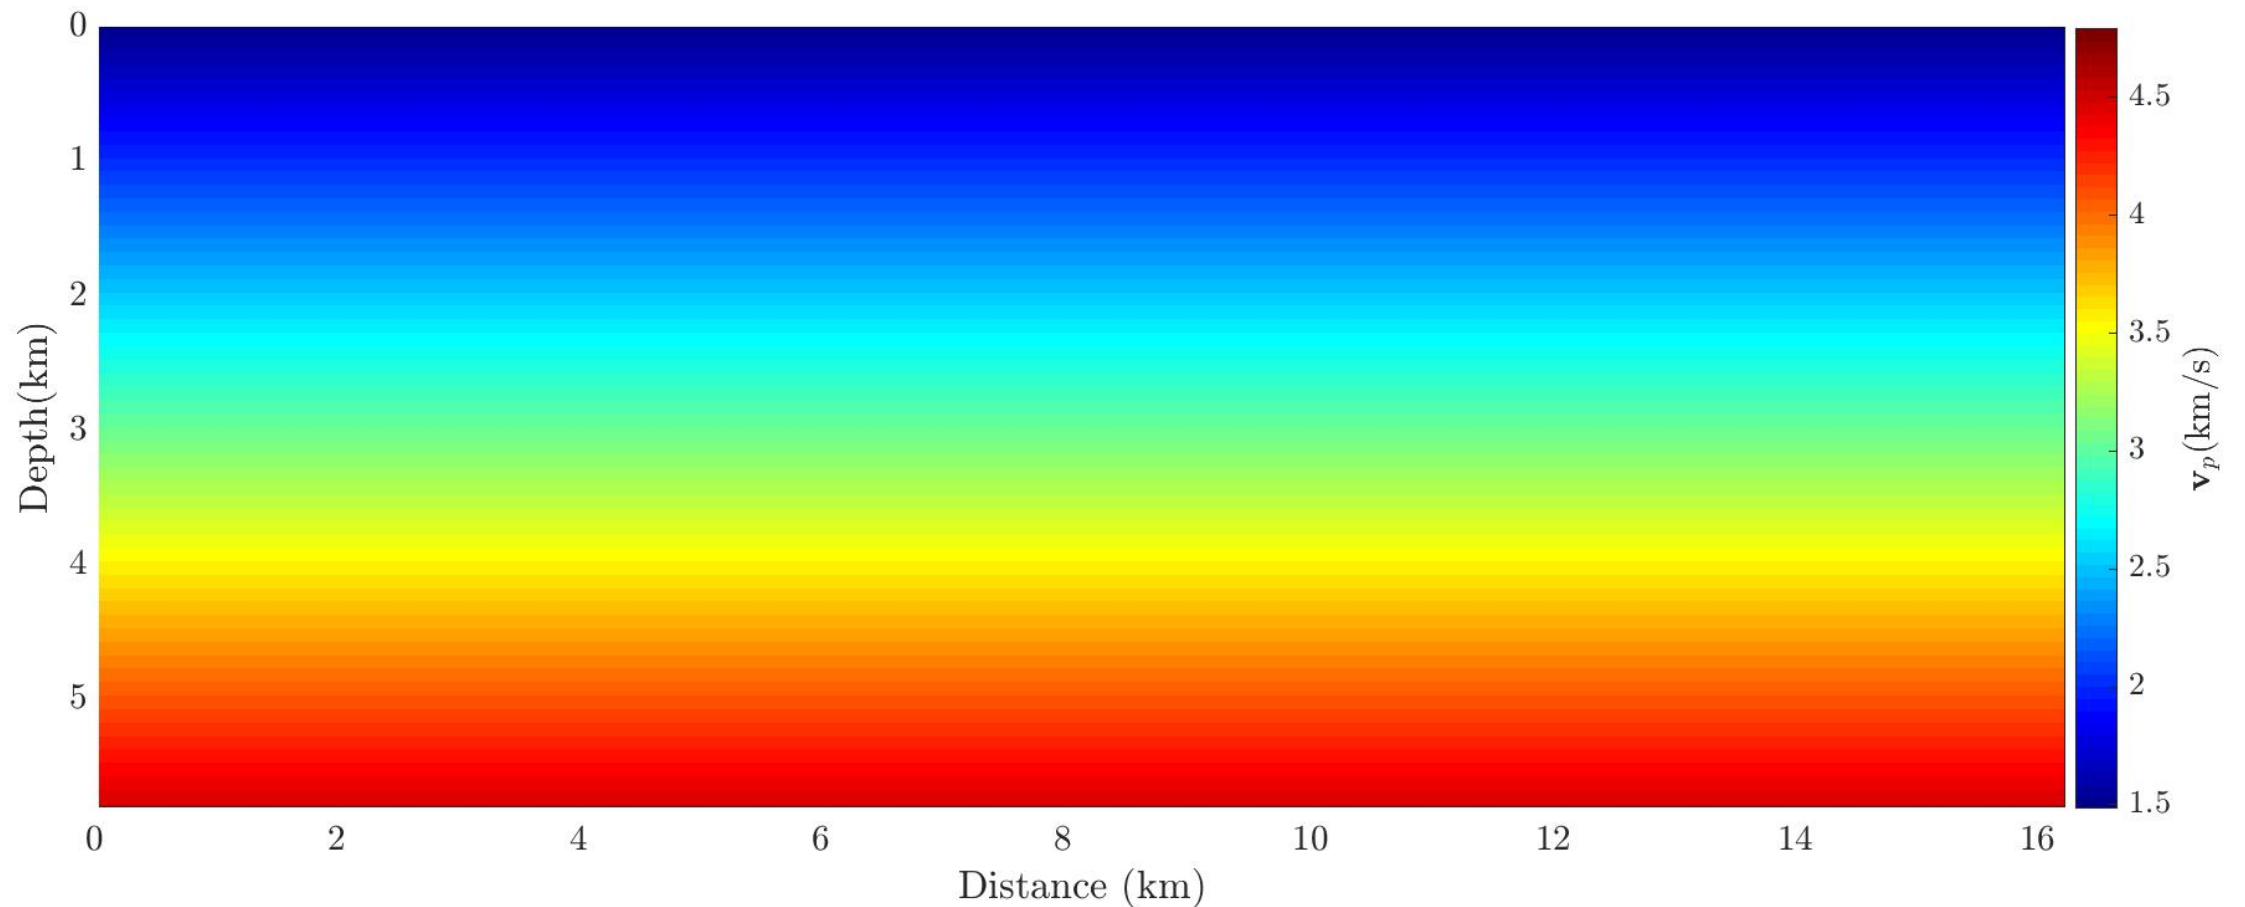

- ✓ The dual variables, as well as wavefields, should be stored on the disk.
- ✓ Original ADMM has a linear convergence.
- ✓ Extracting DA wavefield is challenging for large scale (in time and frequency domain formulation).

2004 BP salt model

- ✓ It is representative of the geology of the deep offshore **Gulf of Mexico**.
- ✓ It has a **simple background** with a complex rugose multivalued **salt body**, **sub-salt** slow velocity anomalies related to over-pressure zones.

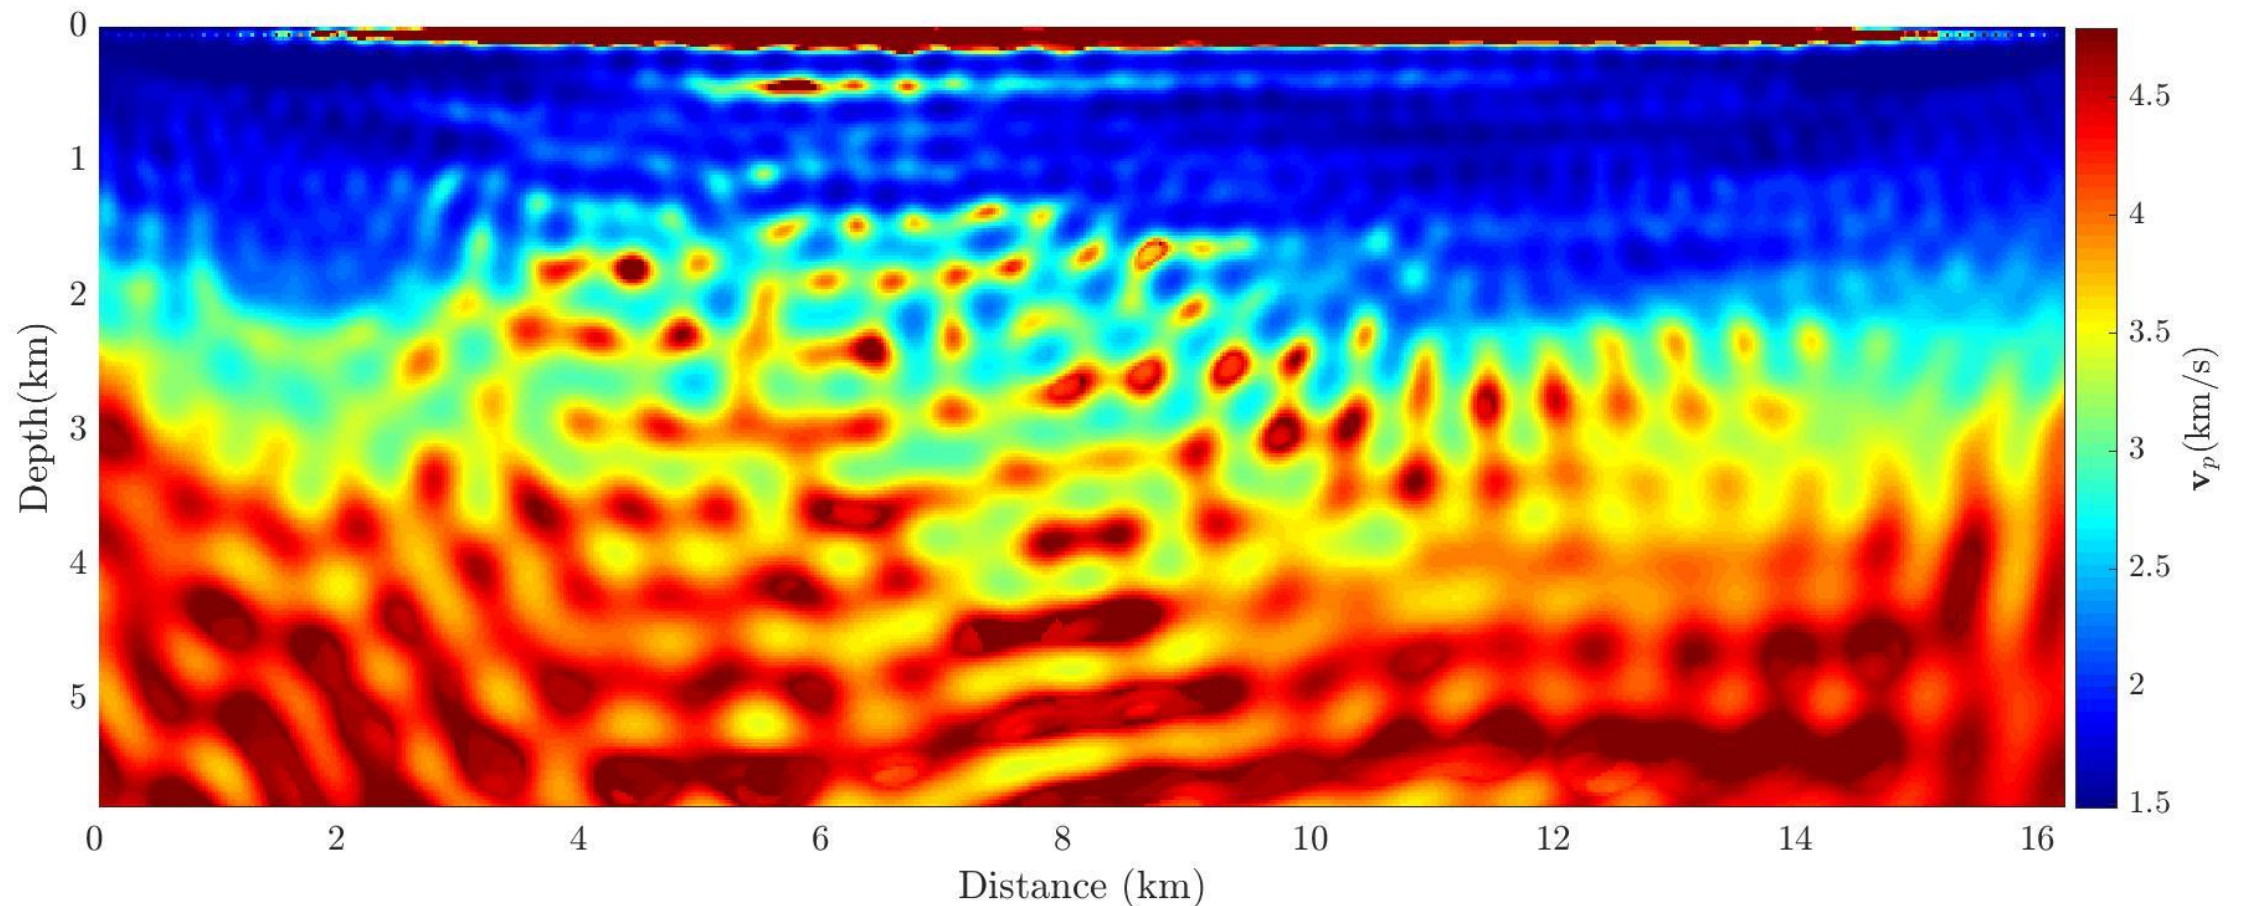

- ✓ **Surface acquisition** with 162 sources and 650 receivers.
- ✓ A 9-point finite-difference staggered-grid stencil with PML boundary condition and anti-lumped mass is used.
- ✓ Inverted frequencies are **3-13Hz** with frequency continuation when batches of 2 frequencies with a 0.5Hz spacing are used and three paths over batches are used.

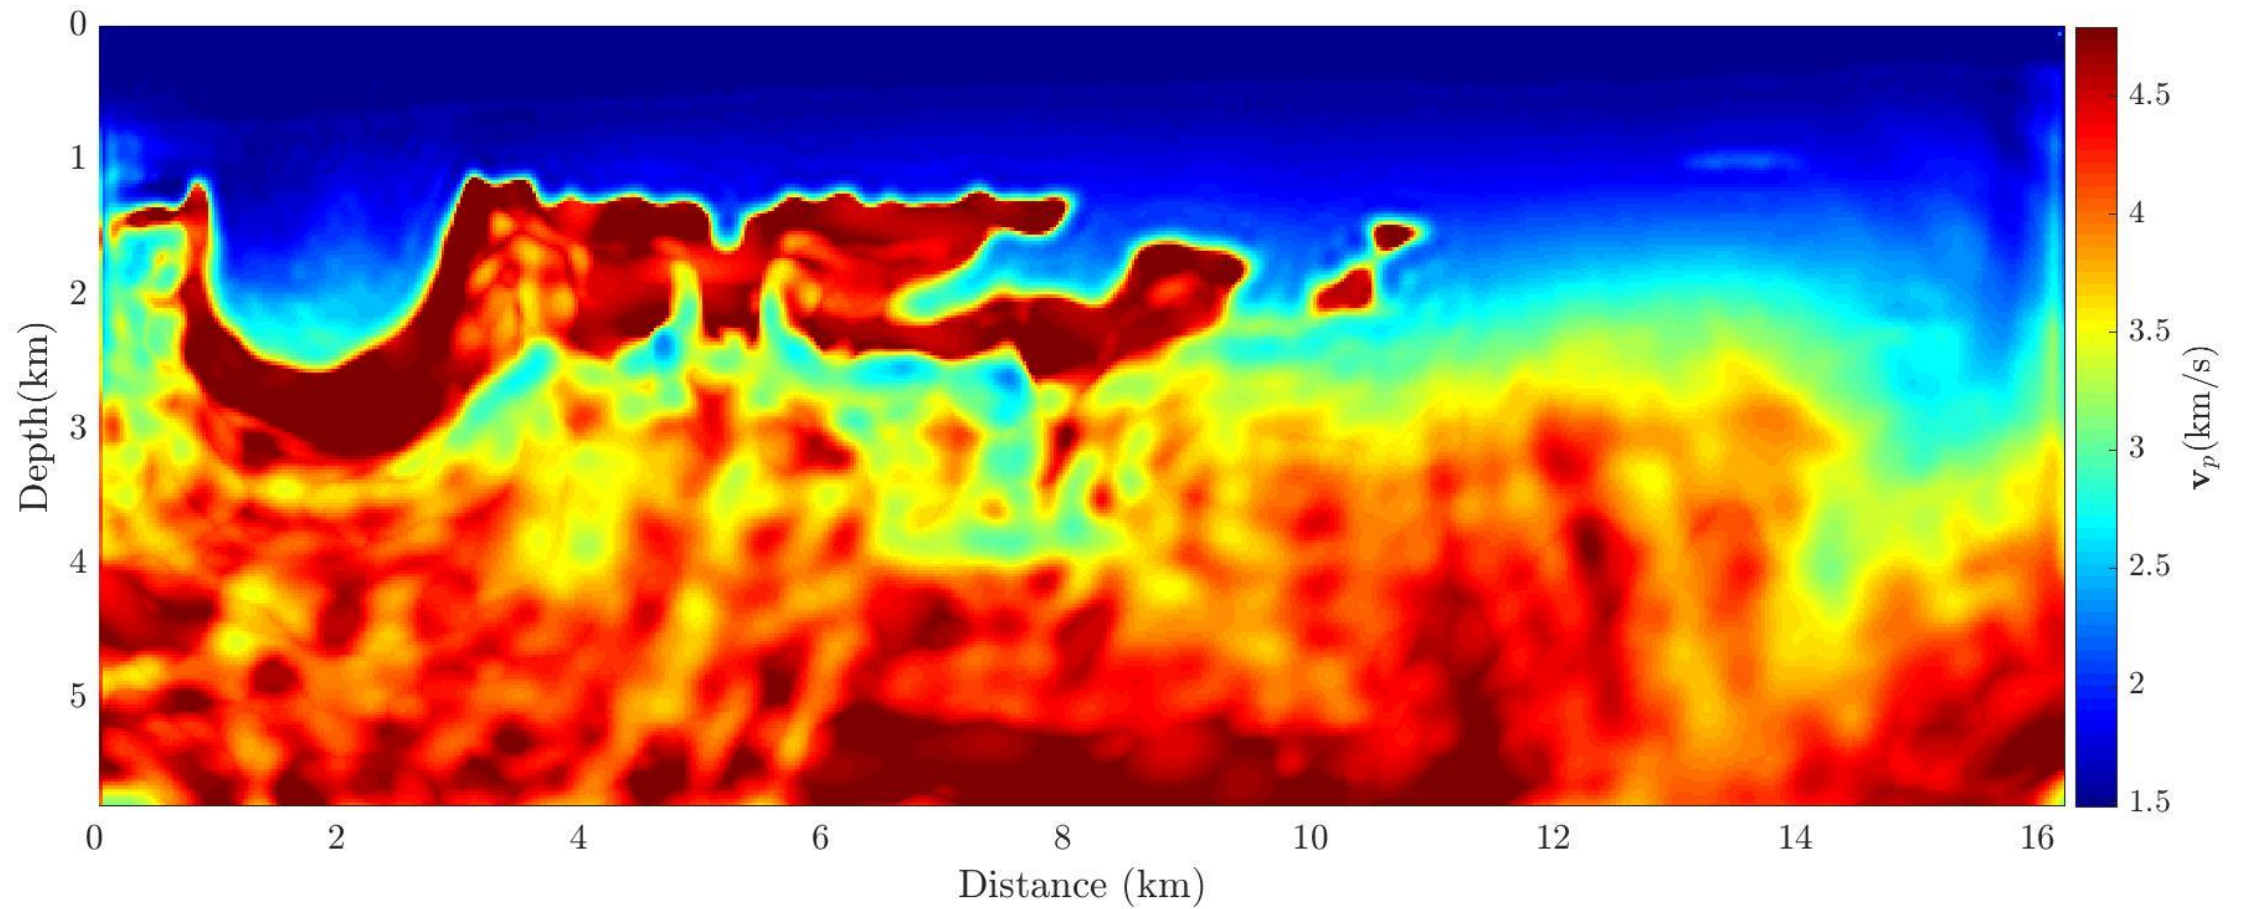

$$\min_{\mathbf{m}} \|\mathbf{P}\mathbf{A}(\mathbf{m})^{-1}\mathbf{b} - \mathbf{d}\|_2^2$$

The model parameters are updated with the **L-BFGS** quasi-Newton optimization and a line search procedure for step length estimation (that satisfies the Wolfe conditions).

The reduced approach FWI is **stuck** in a **local minimum** during the inversion of the first batch.

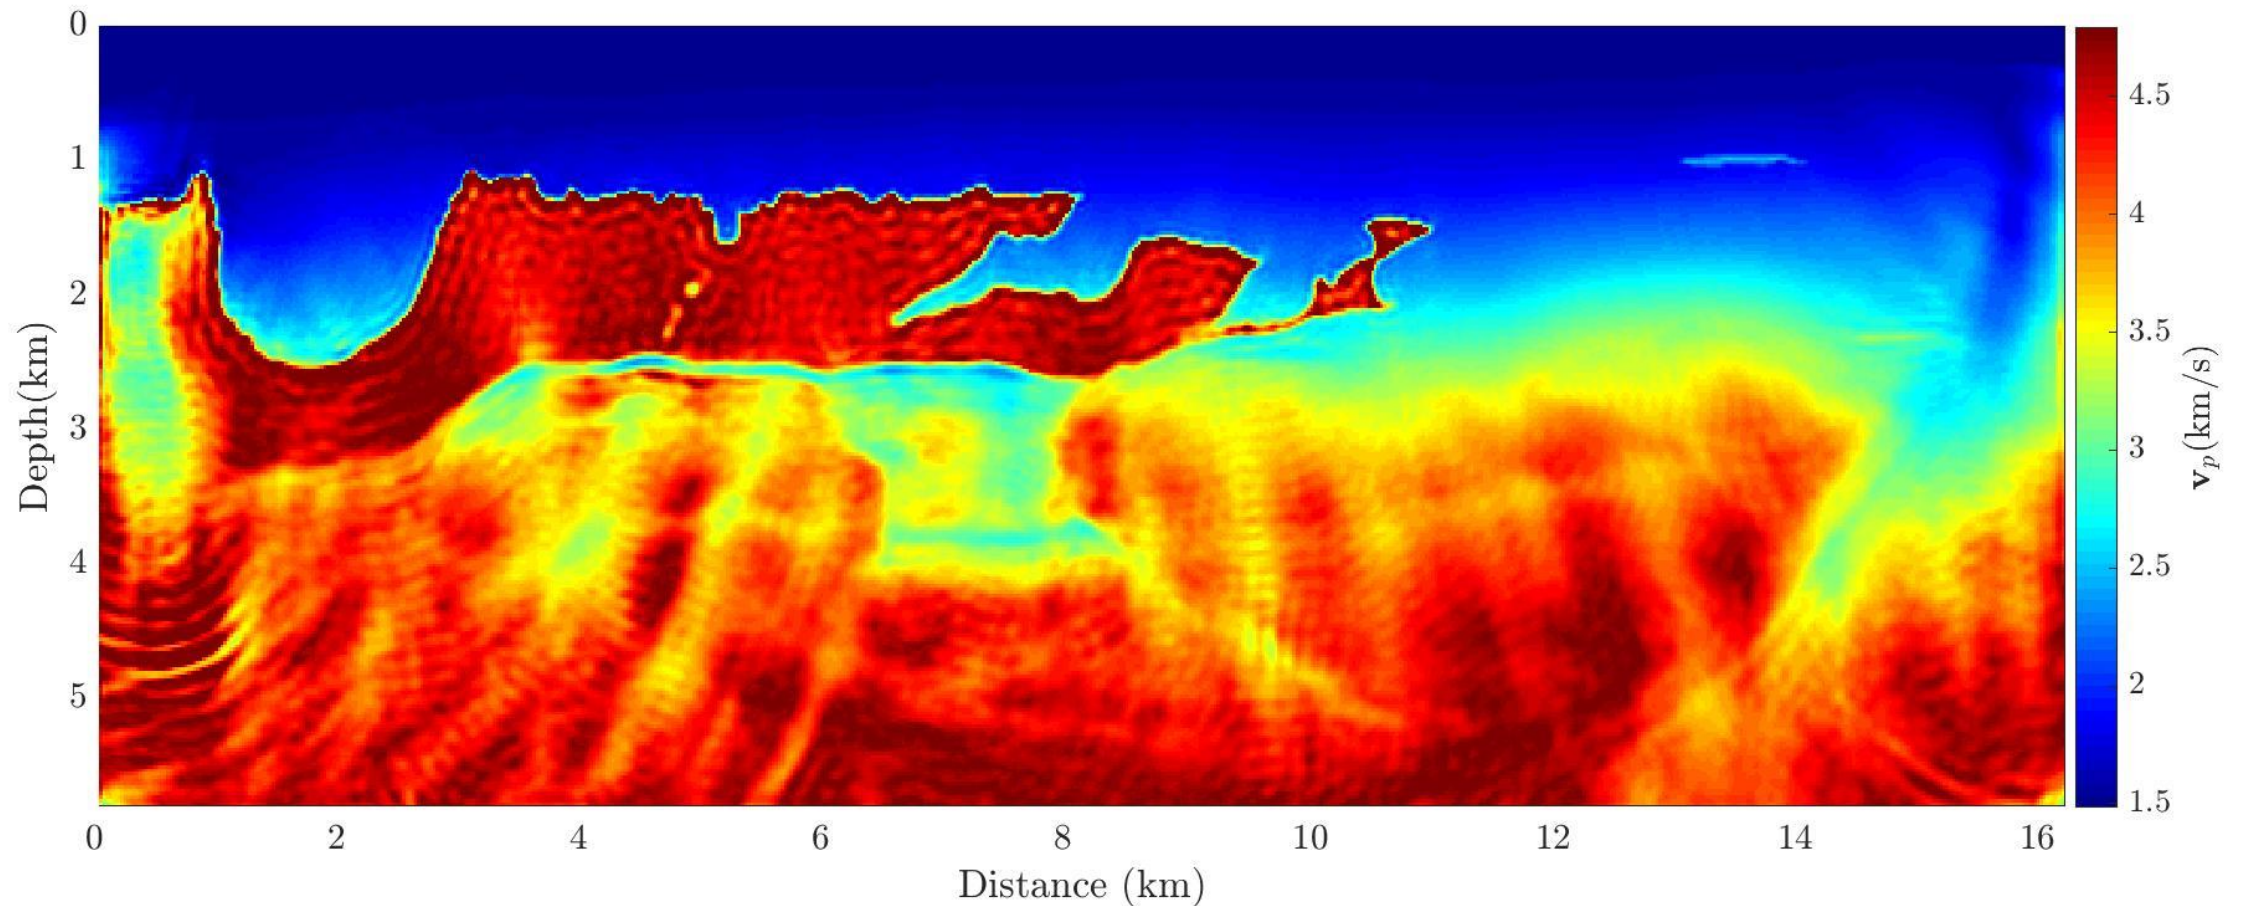

Number of iterations \rightarrow 561

Number of iterations $\rightarrow 288 \rightarrow$ A faster convergence to more accurate subsurface model.

The extracted model still is not acceptable because of the poor illumination of surface acquisition.

Pitfalls and challenges

Nonlinearity

Non convexity and local minima (cycle skipping)

Ill-posedness

Incomplete illumination

Parameter cross-talk

Systematic errors

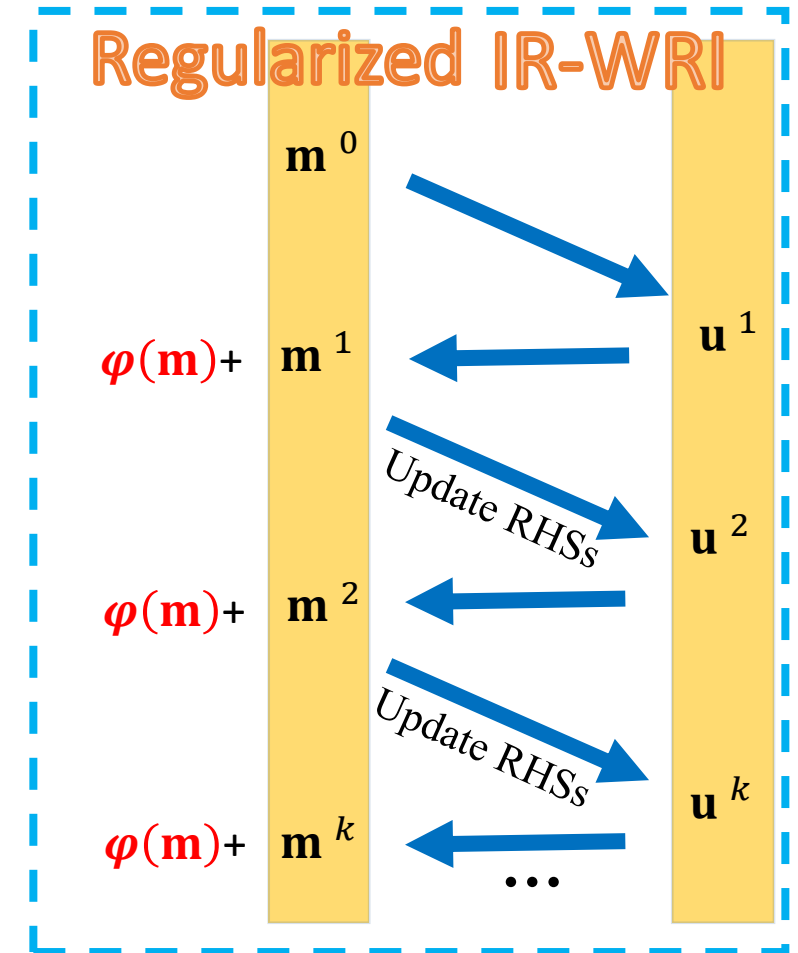

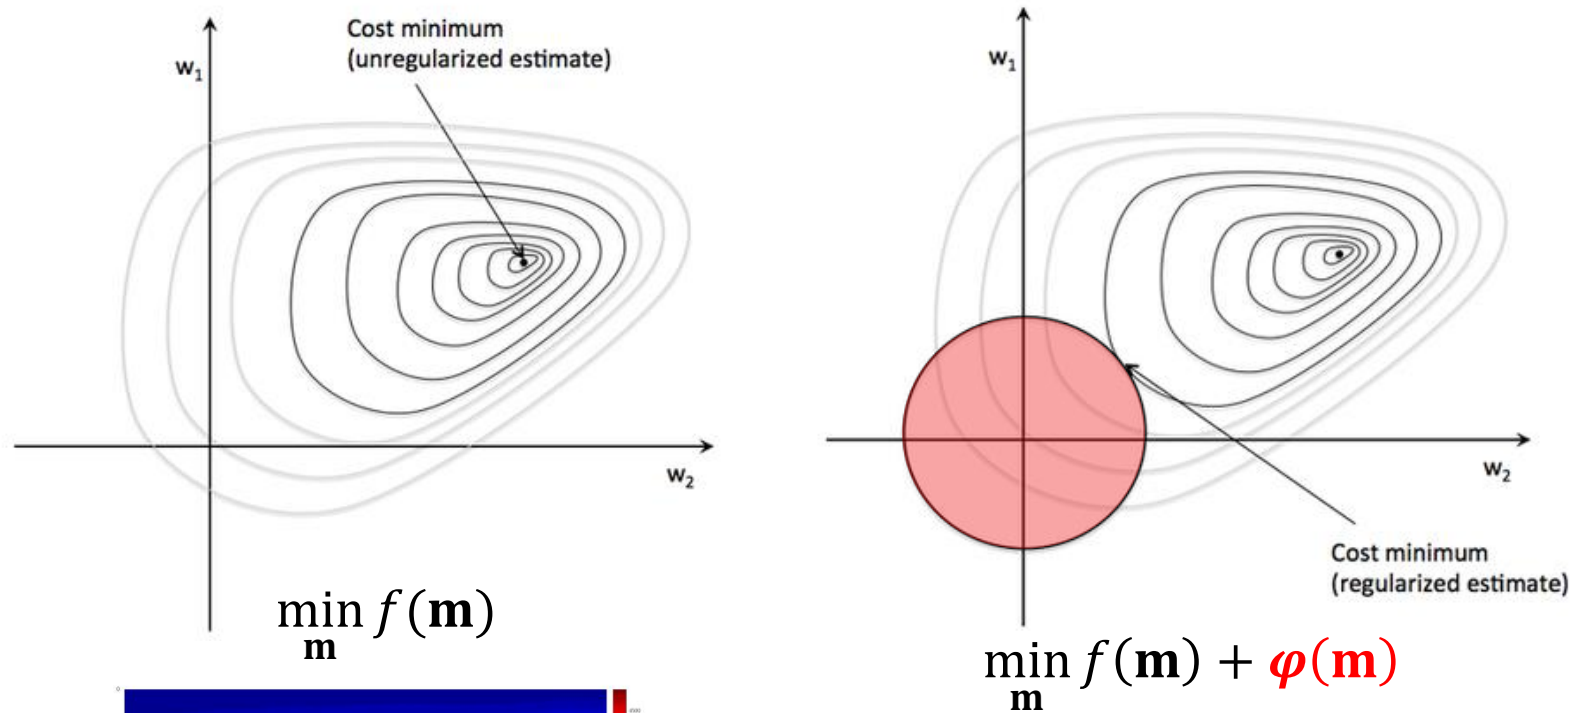

Approximate physics in forward problem

HPC issue

Computational burden

Regularization and adding prior information

- ✓ Because of the **insufficient illumination** of surface data acquisition, some parts of the model can't be reconstructed (there are in the null space).
- ✓ Regularization is a process of introducing additional information in order to solve an ill-posed problem or to prevent overfitting.

Drive the inversion
toward priors of $\varphi(\mathbf{m})$

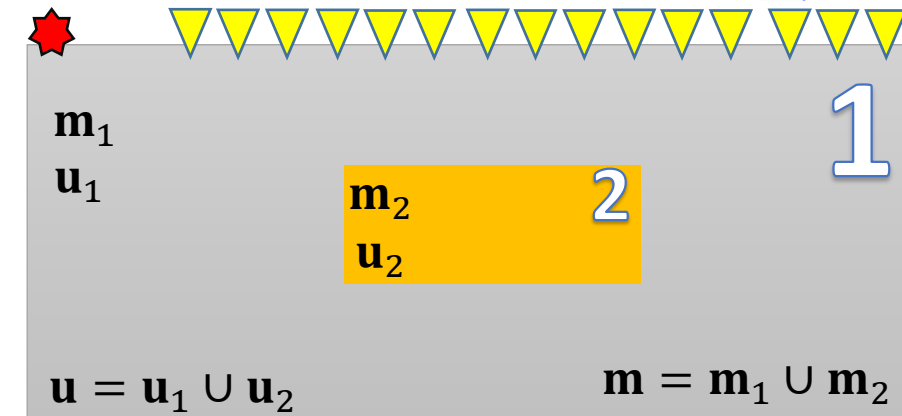

1 Full waveform inversion (FWI) and its challenges

2 Some FWI solution methods

3 Localized FWI or target-oriented FWI

- Here, we want to update \mathbf{m}_2 when a good approximation of \mathbf{m}_1 exist.

1. Data **redatuming** and then FWI.
2. FWI using **local** wave-equation **solvers**.

The diagram illustrates the decomposition of a matrix-vector multiplication into two parallel paths. On the left, a 6x6 matrix $A(m)$ is multiplied by a 6x1 vector u to produce a 6x1 vector. This is shown as a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top. This is equal to a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top, plus a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top. On the right, a 6x6 matrix P is multiplied by a 6x1 vector u to produce a 6x1 vector. This is shown as a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top. This is equal to a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top, plus a 6x6 grid with a 2x2 yellow subgrid in the top-right, and a 6x1 vector with 2 yellow cells in the top.

Multi-block FWI

FWI for sub-domains 1 and 2 can be written as:

$$\min_{\mathbf{m}_1, \mathbf{m}_2, \mathbf{u}_1, \mathbf{u}_2} \underbrace{\|\mathbf{P}_1 \mathbf{u}_1 + \mathbf{P}_2 \mathbf{u}_2 - \mathbf{d}\|_2^2}_{\text{Observation equation}} + \underbrace{\varphi_1(\mathbf{m}_1)}_{\text{Reg. for sub.1}} + \underbrace{\varphi_2(\mathbf{m}_2)}_{\text{Reg. for sub.2}} \quad \text{subject to} \quad \underbrace{\mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1 + \mathbf{A}_2(\mathbf{m}_2) \mathbf{u}_2 = \mathbf{b}}_{\text{Wave equation}}$$

Here we have four primal variables, \mathbf{m}_1 , \mathbf{m}_2 , \mathbf{u}_1 and \mathbf{u}_2 .

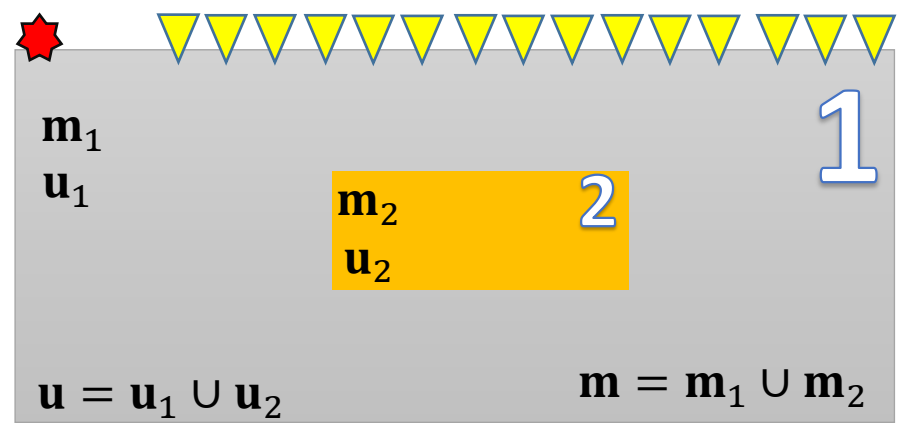

Multi-block ADMM uses the augmented Lagrangian to update primal and dual variables in an alternating mode.

$$\mathcal{L}_A(\mathbf{m}_1, \mathbf{m}_2, \mathbf{u}_1, \mathbf{u}_2) = \varphi_1(\mathbf{m}_1) + \varphi_2(\mathbf{m}_2) + \|\mathbf{P}_1 \mathbf{u}_1 + \mathbf{P}_2 \mathbf{u}_2 - \mathbf{d}\|_2^2 + \lambda \|\mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1 + \mathbf{A}_2(\mathbf{m}_2) \mathbf{u}_2 - \mathbf{b} - \tilde{\mathbf{b}}\|_2^2 - \lambda \|\tilde{\mathbf{b}}\|_2^2$$

ADMM-based multi-block FWI → Solve AL in an alternating mode for primal and dual variables.

$$\begin{aligned} & \min_{\mathbf{u}_1} \mathcal{L}_A(\mathbf{u}_1, \mathbf{u}_2^k, \mathbf{m}_1^k, \mathbf{m}_2^k, \tilde{\mathbf{b}}^k) \\ & \min_{\mathbf{u}_2} \mathcal{L}_A(\mathbf{u}_1^{k+1}, \mathbf{u}_2, \mathbf{m}_1^k, \mathbf{m}_2^k, \tilde{\mathbf{b}}^k) \\ & \min_{\mathbf{m}_1} \mathcal{L}_A(\mathbf{u}_1^{k+1}, \mathbf{u}_2^{k+1}, \mathbf{m}_1, \mathbf{m}_2^k, \tilde{\mathbf{b}}^k) \\ & \min_{\mathbf{m}_2} \mathcal{L}_A(\mathbf{u}_1^{k+1}, \mathbf{u}_2^{k+1}, \mathbf{m}_1^{k+1}, \mathbf{m}_2, \tilde{\mathbf{b}}^k) \\ & \max_{\tilde{\mathbf{b}}} \mathcal{L}_A(\mathbf{u}_1^{k+1}, \mathbf{u}_2^{k+1}, \mathbf{m}_1^{k+1}, \mathbf{m}_2^{k+1}, \tilde{\mathbf{b}}) \end{aligned}$$

These subproblems converge to the solution of conventional IR-WRI, but with a **slower convergence** rate.

An Adaptation of Multi-Block ADMM for Localized FWI

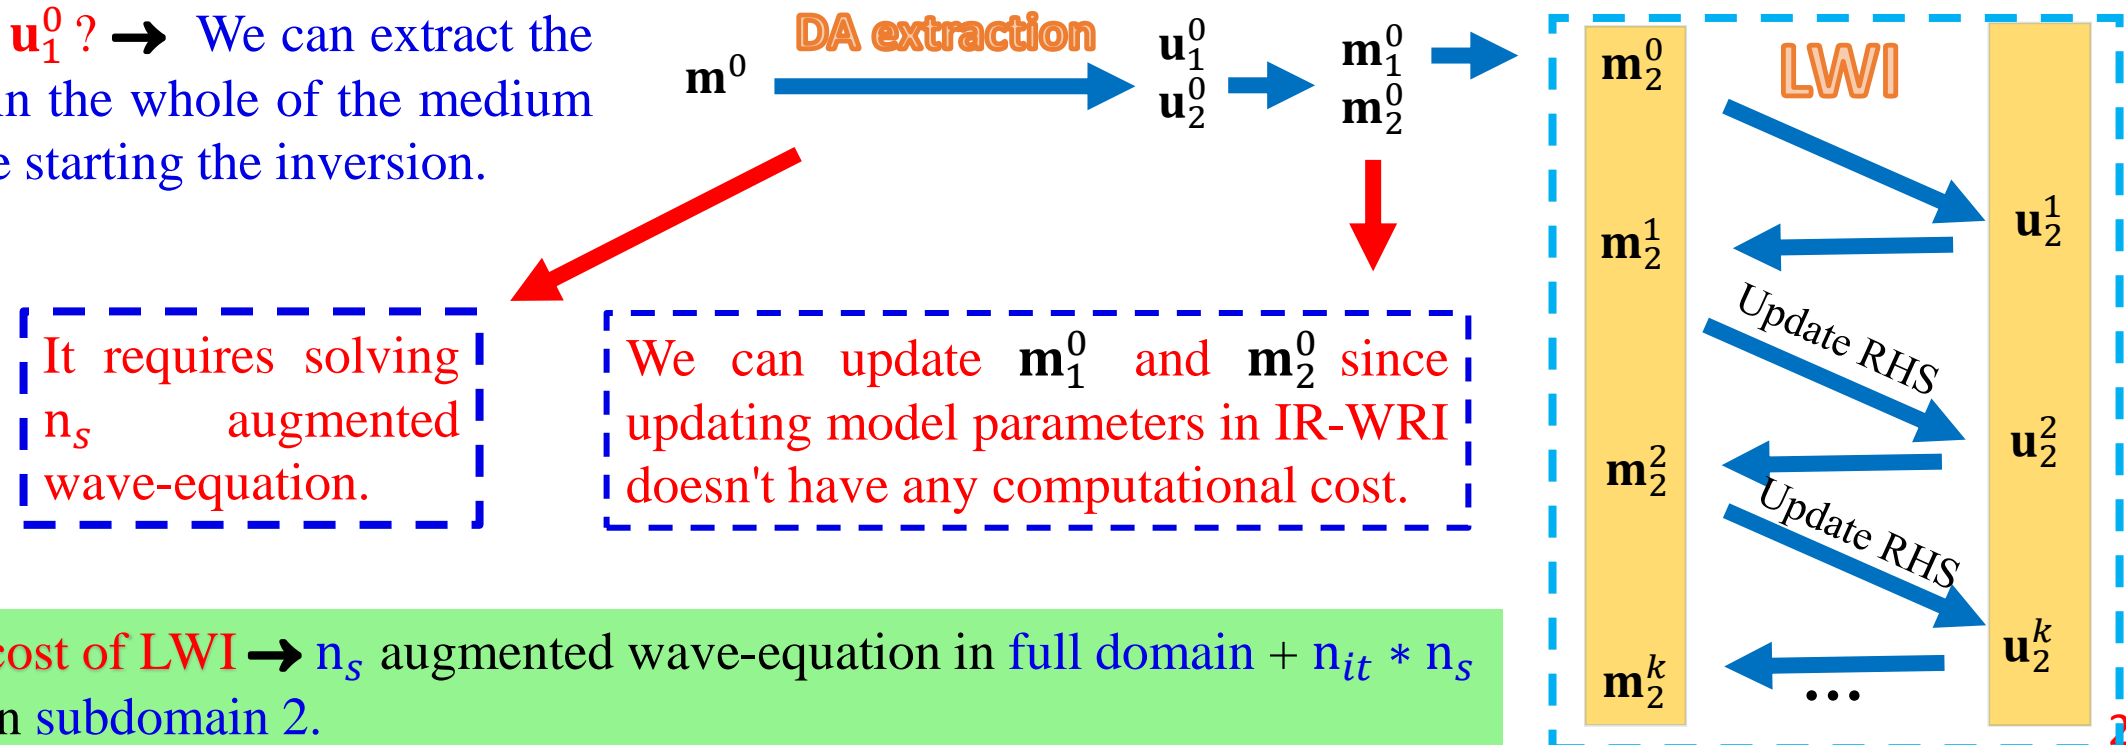

In localized FWI, a good approximation of \mathbf{m}_1 is exist and the goal is to update \mathbf{m}_2 .

Localized Wavefield Inversion (LWI): Keep \mathbf{m}_1 and \mathbf{u}_1 as passive variables and solve the rest of subproblems:

- 1 $\min_{\mathbf{u}_2} \mathcal{L}_A(\mathbf{u}_1^0, \mathbf{u}_2, \mathbf{m}_1^0, \mathbf{m}_2^k, \tilde{\mathbf{b}}^k) \rightarrow \mathbf{u}_2^{k+1} = \underset{\mathbf{u}_2}{\operatorname{argmin}} \|\mathbf{A}(\mathbf{m}_2^k) \mathbf{u}_2 + \mathbf{A}(\mathbf{m}_1^0) \mathbf{u}_1^0 - \mathbf{b} - \tilde{\mathbf{b}}^k\|_2^2$
- 2 $\min_{\mathbf{m}_2} \mathcal{L}_A(\mathbf{u}_1^0, \mathbf{u}_2^{k+1}, \mathbf{m}_1^0, \mathbf{m}_2, \tilde{\mathbf{b}}^k) \rightarrow \mathbf{m}_2^{k+1} = \underset{\mathbf{m}_2}{\operatorname{argmin}} \varphi_2(\mathbf{m}_2) + \lambda \|\mathbf{L}(\mathbf{u}_2^{k+1}) \mathbf{m}_2 + \mathbf{A}_1(\mathbf{m}_1^0) \mathbf{u}_1^0 - \mathbf{y}\|_2^2$
- 3 $\max_{\tilde{\mathbf{b}}} \mathcal{L}_A(\mathbf{u}_1^0, \mathbf{u}_2^k, \mathbf{m}_1^0, \mathbf{m}_2^k, \tilde{\mathbf{b}}) \rightarrow \tilde{\mathbf{b}}^{k+1} = \tilde{\mathbf{b}}^k + \mathbf{b} - \mathbf{A}(\mathbf{m}_2^{k+1}) \mathbf{u}_2^{k+1} - \mathbf{A}(\mathbf{m}_1^0) \mathbf{u}_1^0$

How to extract \mathbf{u}_1^0 ? \rightarrow We can extract the DA wavefield in the whole of the medium one-time before starting the inversion.

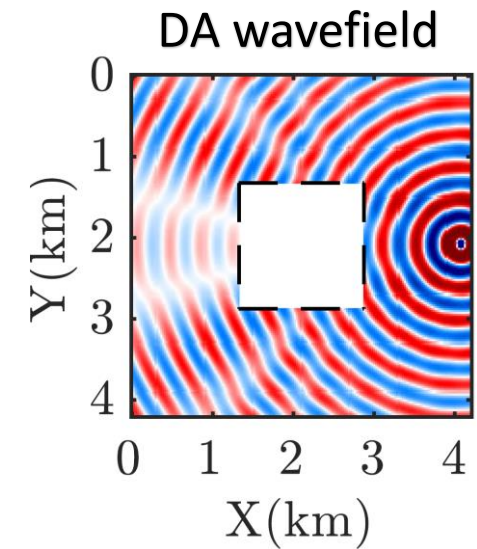

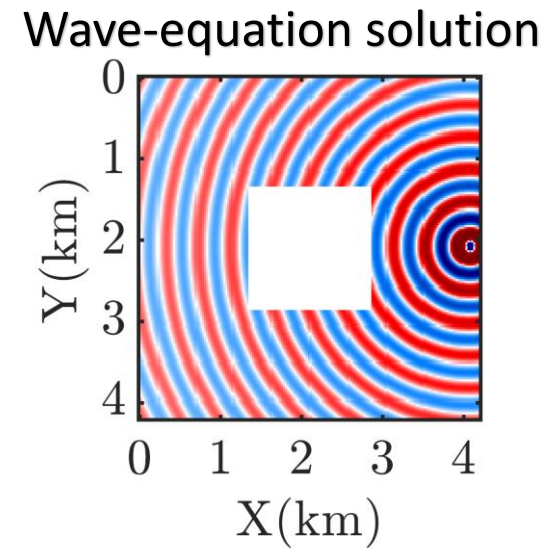

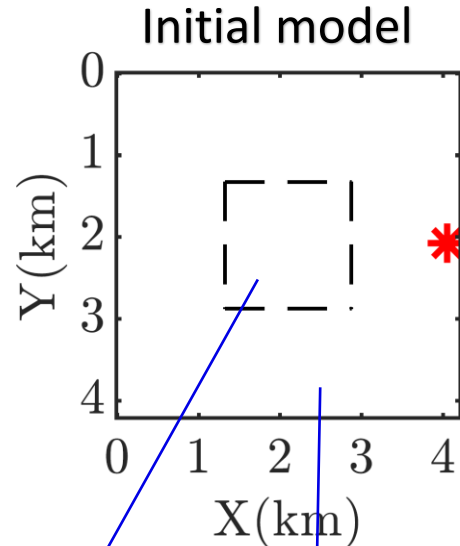

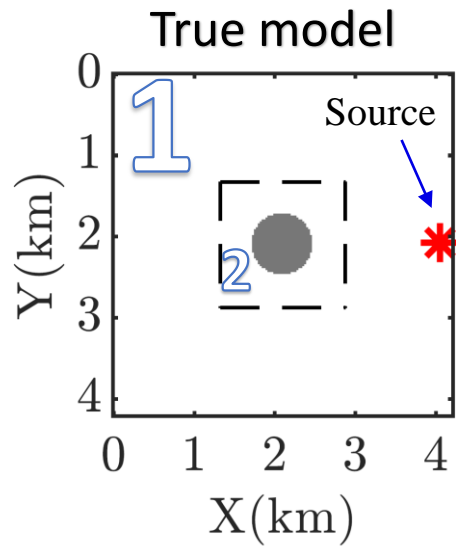

Computational cost of LWI $\rightarrow n_s$ augmented wave-equation in full domain + $n_{it} * n_s$ wave-equation in subdomain 2.

What is missed in LWI?

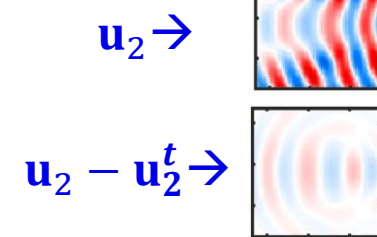

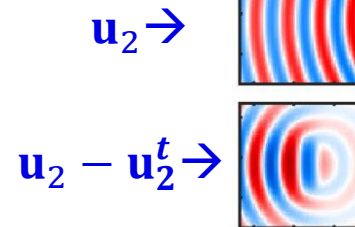

wave-equation \longrightarrow $\mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1 + \mathbf{A}_2(\mathbf{m}_2) \mathbf{u}_2 = \mathbf{b} \longrightarrow \mathbf{u}_2 = \mathbf{A}_2(\mathbf{m}_2)^\dagger [\mathbf{b} - \mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1]$

$\boxed{\mathbf{A}^\dagger \rightarrow \text{The generalized inverse of } \mathbf{A}.}$ $\underbrace{\mathbf{u}_1(\mathbf{m}_1, \mathbf{m}_2)}$

When \mathbf{m}_2 changes, we should update \mathbf{u}_1 , otherwise the interaction of the wavefield between 2 and 1 are missed and extracted \mathbf{u}_2 is an approximation.

$$\mathbf{u}_2 = \mathbf{A}_2(\mathbf{m}_2)^\dagger [\mathbf{b} - \mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1]$$

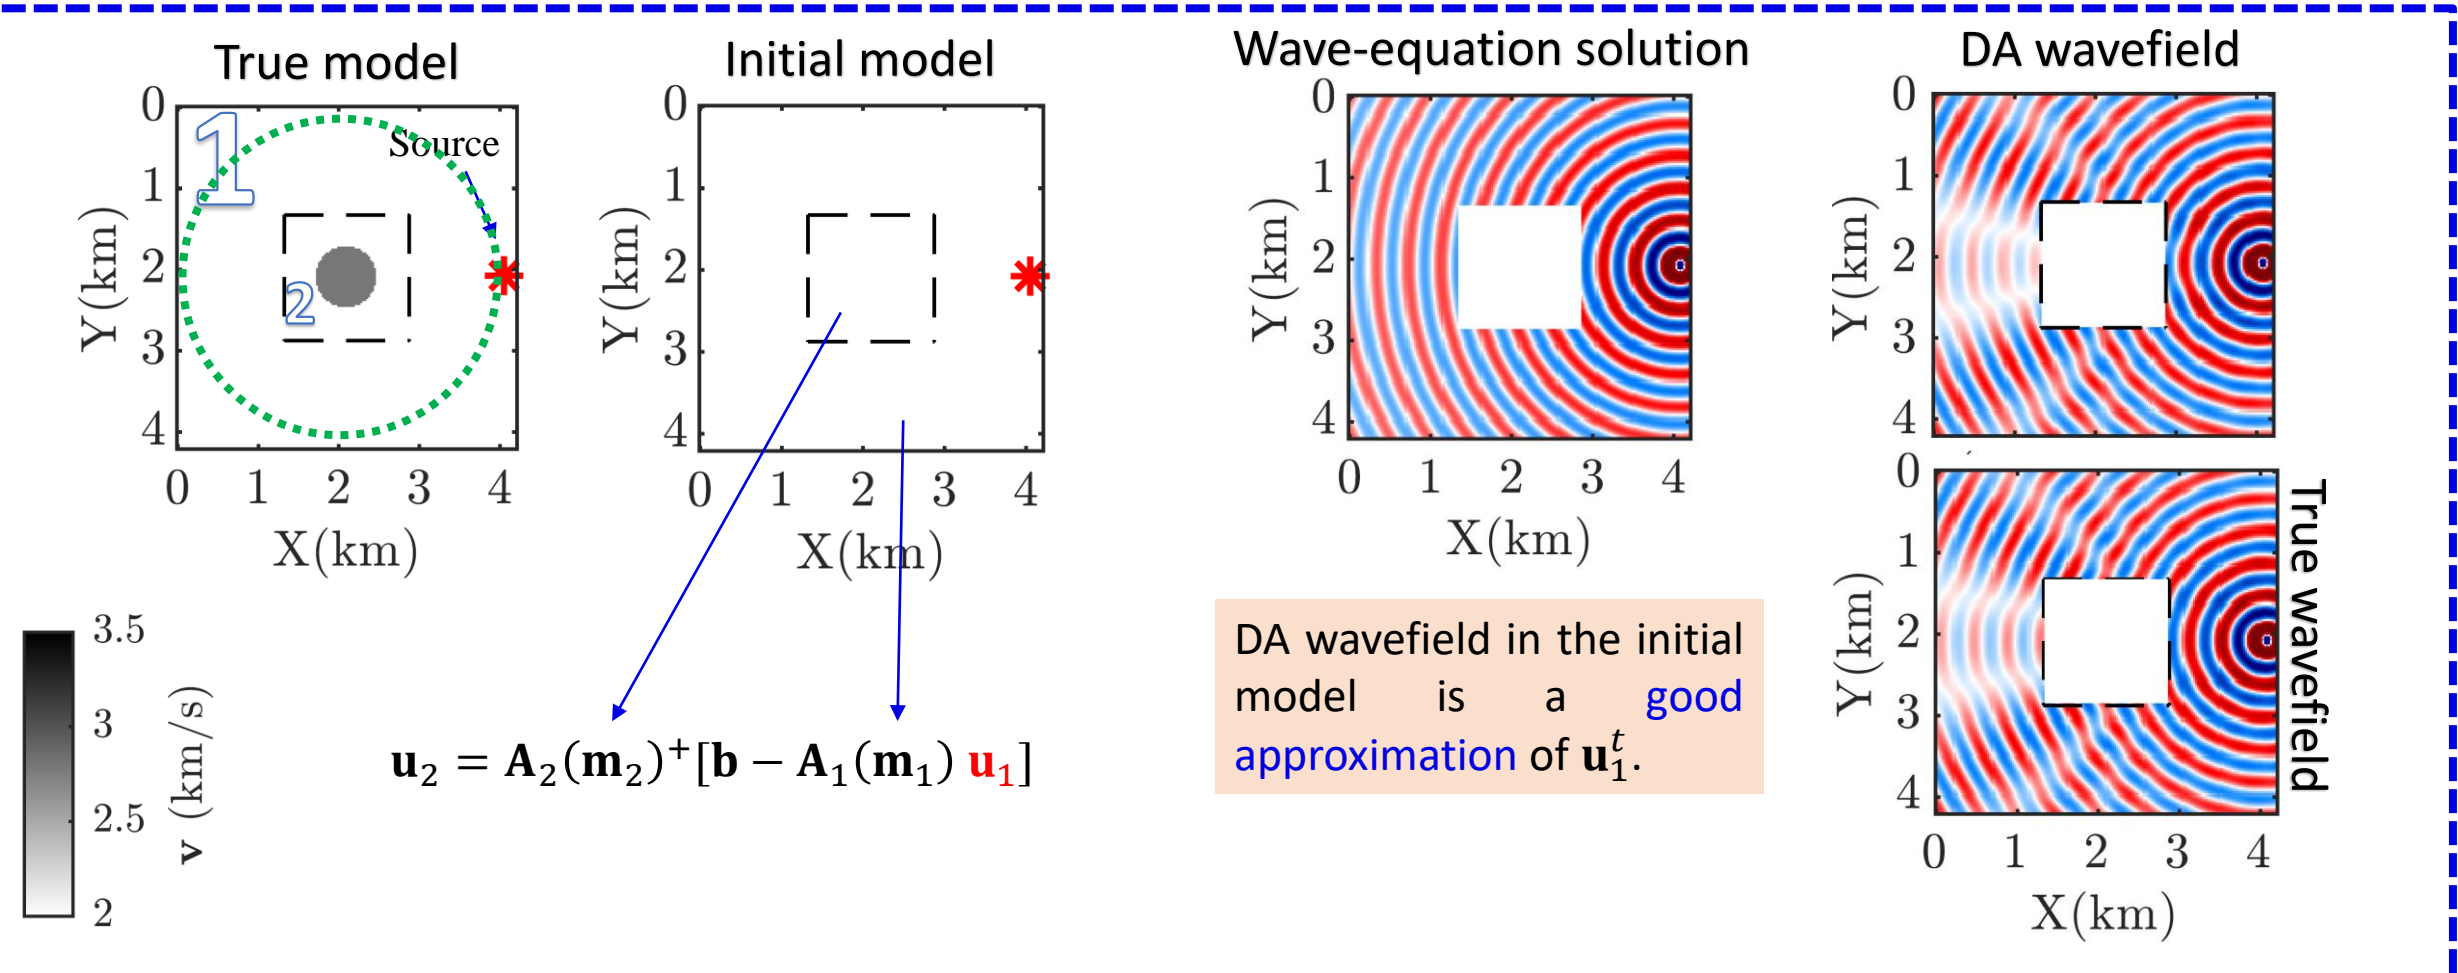

What is missed in LWI?

wave-equation \longrightarrow $\mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1 + \mathbf{A}_2(\mathbf{m}_2) \mathbf{u}_2 = \mathbf{b} \longrightarrow \mathbf{u}_2 = \mathbf{A}_2(\mathbf{m}_2)^\dagger [\mathbf{b} - \mathbf{A}_1(\mathbf{m}_1) \mathbf{u}_1]$

$\mathbf{A}^\dagger \rightarrow$ The generalized inverse of \mathbf{A} .

$\mathbf{u}_1(\mathbf{m}_1, \mathbf{m}_2)$

When \mathbf{m}_2 changes, we should update \mathbf{u}_1 , otherwise the interaction of the wavefield between 2 and 1 are missed and extracted \mathbf{u}_2 is an approximation.

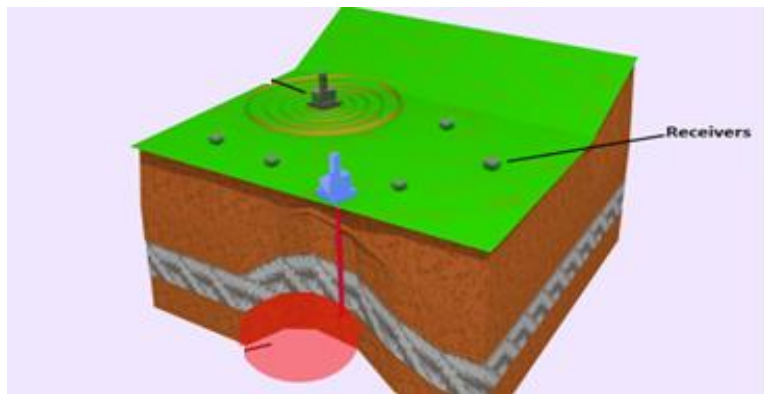

Marmousi II test: a 4D example

The term 4D reflects that calendar time represents the fourth dimension.

Here the goal is to **rapidly** estimate the **local changes** that happen because of injected fluids or gas in the subsurface between a baseline and monitor data.

- ✓ **Surface acquisition** with 57 sources and 650 receivers.
- ✓ Inverted frequencies are **3-13Hz** with frequency.
- ✓ A **10 Hz Ricker** is used as the wavelet.

inverted
models

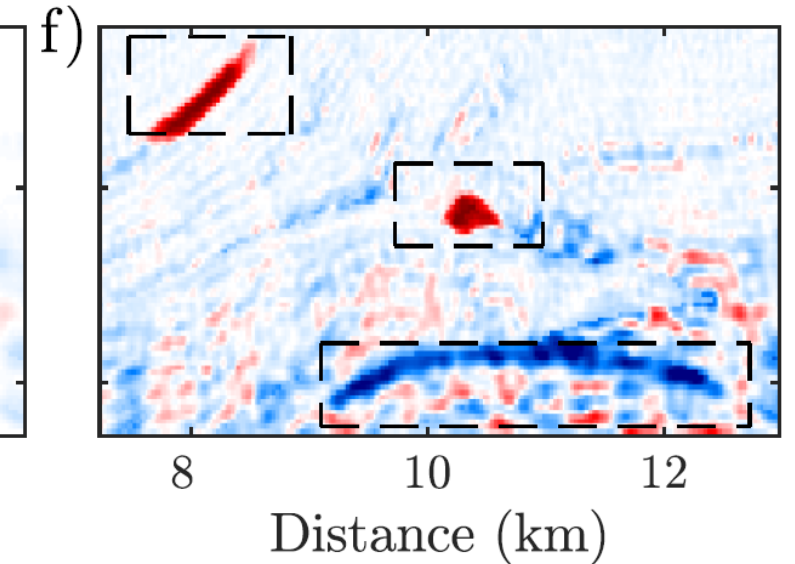

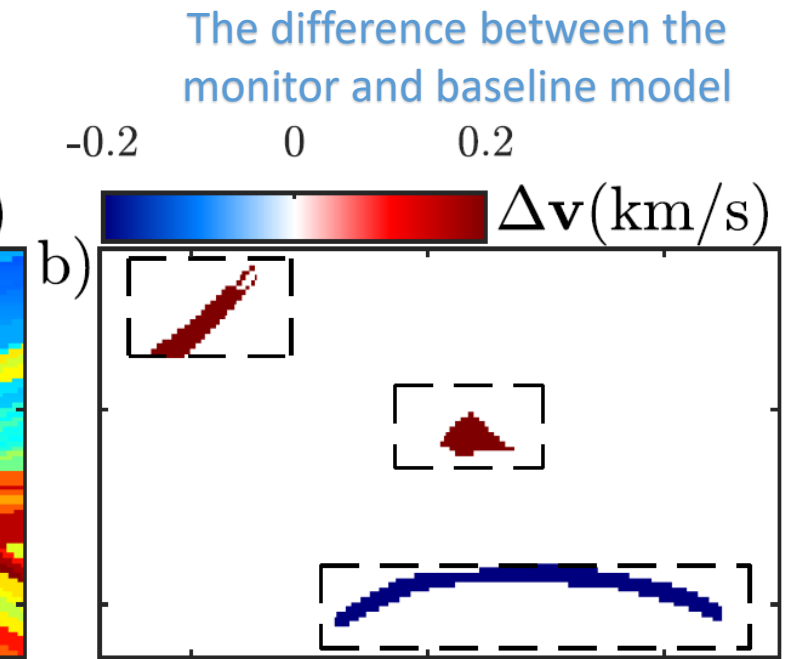

Marmousi II test: a 4D example

- ✓ We use **three frequencies** for the monitor data inversion, [5, 10, 15]Hz, and a successive mono-frequency inversion.
- ✓ We use the **baseline** inverted model as the **initial model**.

LWI reaches approximately to the same model as IR-WR, but **24** times faster.

LWI

IR-WRI

Pitfalls and challenges

Nonlinearity

Non convexity and local minima (cycle skipping)

Ill-posedness

Incomplete illumination

Parameter cross-talk

Systematic errors

Approximate physics in forward problem

HPC issue

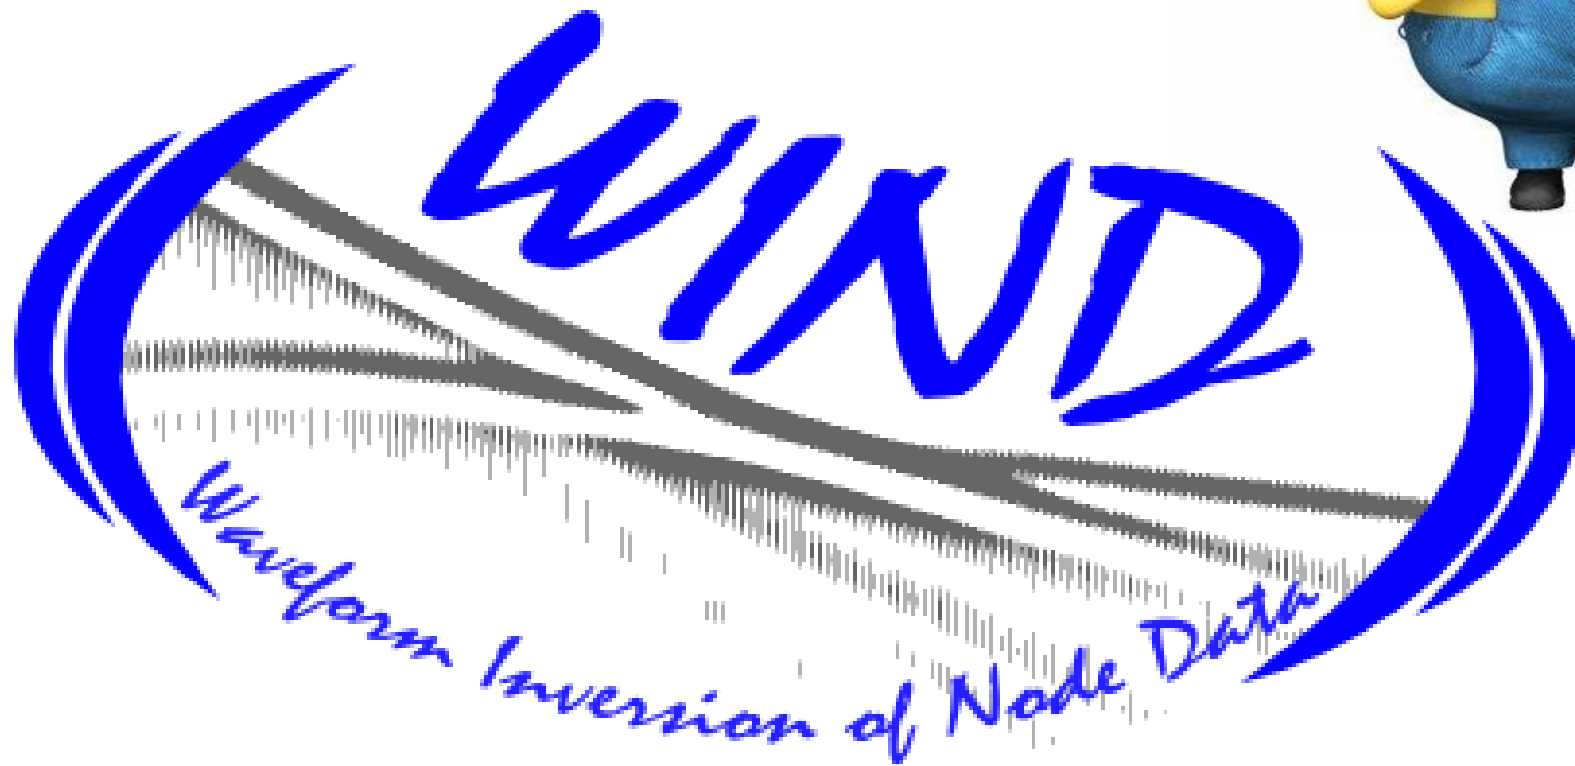

Computational burden

Conclusions

- ✓ FWI is a **high-resolution imaging** technique that has a wide range of applications.
- ✓ We proposed to use augmented Lagrangian for FWI when it is solved using ADMM.
- ✓ We show this formulation can improve the difficulty of the classical formulation with the initial model as well as the difficulties of FWI based on penalty formulation.
- ✓ We show an adaption of **multi-block ADMM-based** wavefield inversion to reduce the computational cost of FWI for target-oriented applications.
- ✓ In this method, the subproblems related to the zone of interest are solved normally at each iteration, while the rest are solved only once.
