## Cubic lifts of 2-vertex

 GRAPHS IN THE CAGE PROBLEM (WORK IN PROGRESS).Martin Mačaj

IWONT23, Edinburgh July 18th 2023

## Introduction

## Overview

- The cage problem
- Voltage graphs and their lists
- Cubic lifts of 2-vertex graphs, "large"girth
- Cubic lifts of 2-vertex graphs, small girth

## Disclaimer

Everything is finite and connected.

## Cages

## ( $k, g$ )-graphs

A $(k, g)$-graph is a $k$-regular graph of girth $g$.
Moore bound $M(k, g) A(k, g)$-graph on $n$ vertices has $n$ at least
$\left(k(k-1)^{(g-1) / 2}-2\right) /(k-2)$ if $g$ is odd, and
$\left(2(k-1)^{g / 2}-2\right) /(k-2)$ if $g$ is even.
A $(k, g)$-graph on $n$ vertices is
a Moore graph if $n=M(k, g)$, a cage if $n$ is the smallest possible value, a record holder if $n$ is the smallest known value.

Cages are known only for very restricted set of pairs $(k, g)$. More in the talk by Robert Jajcay.

## Symetries

Many of record holders are highly symmetric (vertex-, arc-, edge-, flag- transitive/regular).

Theorem (Sabidussi) Graph is Cayley iff it has group G automorphism which has unique orbit and this orbit has size $|G|$.
Theorem Graph is a lift of an l-vertex graph iff it has group $G$ automorphism which has exactly $l$ orbits all of size $|G|$.

Question What is the number of 2 -vertex cubic graphs?

## Lifts

## Lifts

Let $\Gamma$ be a graph with the dart set $D(\Gamma)$. Each edge e consists of a pair of mutually inverse darts $d$ and $d^{-1}$. Each dart $d$ has an initial vertex $i(d)$ and a tail vertex $t(d)=i\left(d^{-1}\right)$.
A voltage assignment on $\Gamma$ with values in a group $G$ is a mapping $\alpha: D(\Gamma) \rightarrow G$ such that $\forall d \in D(\Gamma): \alpha\left(d^{-1}\right)=\alpha(d)^{-1}$.
The lift of base graph $\Gamma$ (w.r.t. $\alpha$ ) is the graph $\tilde{\Gamma}$ with

$$
\begin{aligned}
V(\tilde{\Gamma}) & =V(\Gamma) \times G \\
D(\tilde{\Gamma}) & =D(\Gamma) \times G \\
i(d, g) & =(i(d), g) \\
t(d, g) & =(t(d), g \alpha(d)), \\
(d, g)^{-1} & =\left(d^{-1}, g \alpha(d)\right)
\end{aligned}
$$

## Examples

Cayley graphs are lifts of one vertex graphs.
Haar graphs are lifts of dipoles.
Canonical double covers are lifts of all ones voltages in $\mathbb{Z}_{2}$.
Each graph is its own lift.
$K_{3,3}$ is a lift of the theta graph $\Theta$ (the dipole with 3 edges) with voltages in $\mathbb{Z}_{3}$.

Petersen graph is a lift of the dumbbell graph o-o with voltages in $\mathbb{Z}_{5}$.

## Why to use lifts

$G$ is a group of automorphisms of $\tilde{\Gamma}$ which acts semiregularly with $|V(\Gamma)|$ orbits.
Various invariants (e.g., the girth) of $\tilde{\Gamma}$ can be computed from $\Gamma$ and $\alpha$.

Many record holders are lifts of smaller graphs.

## Cubic lifts of 2-vertex graphs, "large"girth

## Motivation

In 2022 G. Erskine and J. Tuite found new cubic recold holders for girth in 20-32. Their construction was based on Cayley uniform hypergraph and corresponding groups were often of the form perfect $\times$ small (a group $G$ is perfect if $G=G^{\prime}$, i.e., it has no nontrivial abelian quotients).

| $g$ | lower bound | pre E.T. | E.T. |
| :---: | :---: | :---: | :---: |
| 20 | 2048 | 5736 | 12096 |

## Cubic lifts of 2-vertex graphs, small girth

## Motivation

In 2013 P. Potočnik, P. Spiga and G. Verret constructed all vertex-transitive cubic graph on up to 1280 vertices. They found the smallest vertex-transitive and Cayley $(3, g)$ graphs for $g \leq 16$.
Idea For small $g$, find the smallest $(3, g)$ graph which are lifts of 2-vertex graphs.

## Some remarks

Small groups are (usually) far from perfect (e.g, they are solvable, nipotent or abelian) and there are many of them.
P.S.V. developed techniques how to deal with them.

There are neccessary condition on the rank of the voltage group.

It is possible to do induction on groups with a central involution using 2-cohomology (or GAP).

## Semiedges

When doing lifts, it is extremally useful to consider base graphs with semiedges. A semiedge is an edge with incident vertex on just one side. It consists of one self-inverse dart. Voltage on a semiedge is an involution (different from $e_{G}$ ).

There are three cubic graphs on 2 vertices with semiedges: $>-<, \mathrm{o}-<$, and -0-.
(In the cage problem, multiple edges and loops in lifts disappear due to condition on girth. Semiedges have to be explicitly forbidden, otherwise the problem becomes trivial.)

## Girth 9

Voltages on semiedges are $a, b$ on the left, and $c, d$ on the right. The voltage on the edge can be 1 . Voltages are all different.
Cycle of length 9 in $\tilde{\Gamma}$ implies a word in 1, a, b, c, $d$ of length 9 which in $G$ equals 1 . Each possible word gives rise to a shorter cycle.
$1=a b a b a b a b a=a^{a b a b}, 1=a$
$1=a b a 1 c d c d 1, a b a=d c d c, 1=a b a a b a=d c d c d c d c$, length 8
$1=a b 1 c d c d c 1, a b=c d c d c=b a, 1=a b a b$, length 4
$1=a 1 c d c d c d 1, a c=c d c d c d c=c a, 1=a 1 c 1 a 1 c 1$, length 8
$1=a b 1 c 1 a 1 c 1, b a=c a c=b a$, length 8
$1=a b 1 c 1 b 1 c 1, a b=c b c=b c$, length 8
$1=a b 1 c 1 a 1 d 1,1=b c a d a, b c=a d a=c b$, length 8
$1=a b 1 c 1 b 1 d 1,1=d a b c b$, length 8

## What next?

- Finish the computations for small girth.
- Do more thorough computations for "large"girth.
- Look at lifts of larger graphs with semiedges.

## Thank you

## for Your attention
